If you have good posts, I would get a vent pipe mount from RS and connect it to a post. The mount should not have any vertical load on it. You could also get some 5 - 6 inch 1/4 inch screws and fasten the pipe that way after drilling holes in the pipe. If the post won't support the pipe, it won't support it fastened to rails either.

Sounds like a bigger weight would help.

depends... shoot the weight without the fish line and see how far it goes, that is the max you can get... if that's not enough try new tubes, those things do age and lose stretch... or longer tubes. for more height without the line try less weight and see if that gets where you need.

then add the fishing line and see if that drags it down too much... if it does you need less drag or lighter line. either take the line out of the reel and let it spool free or unroll it on a smooth surface so it doesn't have to spin the roll.

An interesting question, and a fairly good answer within limits. I used to do a lot of this sort of thing in the special effects industry (why yes, you CAN launch a refrigerator with bungee cords).

Here are the physics things to think about.

The amount of energy you can put into the projectile is determined by:
a) How far you pull back
b) How hard you had to pull (i.e. spring constant of the tubes)

To a first order, Q = 1/2 * Peak Force * distance pulled back

That energy gets transferred to the projectile as kinetic energy.

To a first order, Q = 1/2 * Mass * V^2

Then, the energy gets converted back to potential energy (height) and lost through air drag and pulling the line out. For slow speeds and small things, the line drag is probably dominant.

By the way, if the pull is about 10 lbs and you pulled back 18", with no air or line drag, a one ounce projectile will go to about 36 meters (120 ft)

A little bit of line drag makes a huge difference. a one ounce drag, essentially doubles the weight of your projectile. For the example, that would change your max height to about 19m (60ft)

If you had a 2 ounce projectile, on the other hand...with no drag, you get to 19m, but the 1 ounce drag only brings you back to 12.4 m (40ft)

Air drag is a smaller order effect.

force in lbs = area in square feet * v(mi/hr)^2/391.. Your one ounce weight is moving about 60 mi/hr at launch (9 lb/sf), but is less than a square inch, so it's about an ounce of drag, but it drops off as the square, so as the projectile slows, the drag drops off..

A heavier projectile goes slower, so that helps on the airdrag too.

Going back to 1 oz, no line drag, but counting air drag for 1" diameter, 27m or so height (about 2 seconds after launch, as a cross check)
1 oz, 1 oz line drag, air drag, 15.5 m
2 oz, no line, air drag, 1" diam, 18.8 m
2 oz, 1 oz line, air drag, 11.6 m

So this should give you a feel for the relative effects of line drag and air drag and projectile mass. I did the calculations with a simple spreadsheet in Excel that numerically integrates the physics equations with very short time steps.

> or plumbing sections will actually work.

I am puzzled that you could not find a clamp that would fit your mast. The electrical dept. should have U clamps, and single screw conduit clamps, some at least which should provide a reasonable fit over your mast. If you must, get the size which may seem too small and either use spacers between the clamp base and wood, or simply screw the screws in tight even if the clamp base doesn't press fully against the wood as you might prefer.

Also, you might want to screw a bit of 2x4 to the fence cross piece in such a manner as to provide a base on which the mast can set.... otherwise it might be possible for it to slide down in the mounting clamps you use.

Good luck.

How high are you trying to go? With everything in my favor (wind, etc.) I could get over about a 50 foot branch with a wrist-slingshot and a 1oz weight. And I think I was standing on a 12 foot ladder to do it, and this was a "best ever" shot.

Having the line catch on anything - grass, leaves, etc., is a major downer. If there's no brush on the ground you might get a little more height by spooling some line out in front of you.

Others here regularly claim being able to get 100+ feet with a slingshot. I never said out loud that they're exaggerating, but I know I could just barely do half that. To get to 100feet I went straight to a tennis ball cannon.

Tim.

I couldn't get 50 feet with mine. I figured the line was too old, but
I realized the sling was way overrated. I can do much, much better
with a rod and reel. My favorite tool was a Bear 76er Bow and Arrow
with a short string. It had a 50 lb pull and I could place an arrow
with a screwdriver handle on the tip where ever I wanted it.

The best was a converted shotgun. I took a shotgun shell and took out
the shot, folded the plastic outer shell over the inner shell and
stuck a wood dowel into it. On the far end of the dowel was a
screwdriver with an eye hook onto which I tied a string. It cleared a
100 foot tree with room to spare, but I was afraid of the possibility
of damaging the gun itself so I only tried this once.

Wow, a shotgun. I wouldn't be so much scared of damaging the gun, but
instead of the gun blowing up in my face!

The tennis ball cannon I use is very very similar to the CSV19 at
http://www.antennalaunchers.com/ and I am very very happy with it.
It's not so much a "point above a crotch in the tree and hope the ball
goes through" but "just shoot the ball and line over the tree".

Tim.

Jim's calculations have confirmed something I've consistently experienced: my homebrew EZ-Hang has never really lived up to my expectations, or should I say the expectations that others have set for the performance of the thing. (For the record, my homebrew device is an exact copy of the famous EZ-Hang.)

For the past three Field Days, which is when I've used the thing, the maximum height I've seemed to attain is around 50 feet-- right in the ballpark for a 1 oz. weight with line and air drags. No matter what I've tried, that's the limit of height for the parameters of my situation.

Thanks, Jim.

Wouldn't that be damaging the gun?

The dowel I used in the barrel was a bit smaller so it wouldn't get
jammed. I imagine if it were a larger diameter, it would have
traveled further. Completely filling the barrel would make me expect
an uncontrolled explosion...

The arrow had a screwdriver that had the shaft trimmed and tapped for
the screw thread of the arrow head.

The stick had a hole drilled in it and the phillips screwdriver stuck
inside the dowel and glued.

Suggest you try a fishing pole. I used a zebco casting rod I bought
new for my wife. Now my favorite antenna pole.
I put my L up over 50' this way. Use 6 pound test line. Heaver line
weights too much. even 4 is better. Get a large washer. 2" or so.
Tie it on. cast up . If you miss your spot let the washer fall to the
ground. Do not reel back thru the tree. Cut off washer. reel back and
tie on and try again. The washer weights enough so it doesn't get
caught easily in trees. It goes so far be careful you do not damage
others cars or homes. It never broke off. When you get your spot tie
on Thin nylon cord and reel it back. Then a larger rope. The washer
rolls as it falls preventing tangling. Try it in a shorter tree for
practice. fishing sinkers do not work well, they wrap around
branches.

4838. Full-wave coaxial loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-05-18 18:21:57 UTC
From: John Poet <tcsshortwave@gmail.com>
Message-ID: <03d207cb-033f-4456-8990-9fe2f6719471@25g2000hsx.googlegroups.com>
Source record: 25460

I want to erect a full-wave horizontal loop antenna for use around 3.5 mHz (as an NVIS antenna). The problem is, I don't have quite the space to configure such an antenna, which would be somewhere around 280 feet long using normal wire. (Don't have my actual calculations in front of me, but they are roughly these dimensions).

I've gotten the idea that I could shorten the physical requirement, by using RG-58 coaxial cable instead of regular wire, and taking the .66 velocity factor into account--- turning an electrical length of about 280 feet into only around 180 physical feet of RG-58. (I have a 1000-ft reel of this stuff). It would be fed with 300 ohm parallel lines to an antenna tuner.

The questions, to those who may be more well-versed in the theory of antennas, are 1) is my reasoning on the V.F. sound? and 2) if I construct this, should I use the center conducter of the cable as the active element, or the shield, or connect them together? and 3) Would the shielding on the cable have any effect on the center conductor being used as the antenna element?

1. no
2. you could use the shield or connect them together.
3. yes, it would make it not work worth beans.

the velocity factor only applies inside the coax, you can't use that to
shorten the antenna.

The velocity factor applies to differential transmission
line currents, not to antenna currents which are common-
mode. Instead, it sounds like you need a loading coil
opposite the feedpoint.

4841. 1Hz click external noise?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-05-18 21:39:17 UTC
From: Lumpy <lumpy@digitalcartography.com>
Message-ID: <69bm1pF31gm1fU1@mid.individual.net>
Source record: 25463

Any guesses as to the origin of the mystery
noise bugging me this morning would be apprec.

I'm hearing an S9 "click" at just about
once per second, everywhere on 20meters
where there's not a powerful station's
signal. It clicks for maybe 3-5 seconds
then stops for a few seconds. Not always
symmetrical (3 sec noise ~ 10 sec no noise).

Click sounds like what I'd imagine a charging
and regularly discharging capacitor might do.

Freq independant, it's everywhere on the 20m phone segment.

S9+ stations seem to override the click.
S7 stations don't override, the click
comes right through and clobbers reception.

Station is "backyard remote", battery powered,
asymmetrical wire dipole.

I found some recordings of electric blanket
noise via k0bg's site. It sounds very much
like those recordings. Both of the elec blankets
in my home are off and unplugged. Neighbor elec
blankets? They would be probably 100' away from
the closest point to my antenna.

Noise just started this morning. No new elec
or mechanical devices running at my home.
Turned off the A/C, fans, elec fence, light
dimmers, pool filter etc. Three computers
run inside the house, as they have for
years.

Anyone have a guess at this 1 Hz click noise?
TIA -

Hi Lumpy,
I had something very similar a couple of years ago. Noise was burst about a second apart but continuous unlike yours. I went throufg everything in the house that could cause it. This went on for a couple of months until I was riding down a road about a mile from the house and heard it on my cars AM radio. It was coming from the ranch I was riding by. I am pretty sure it was from an electric fence charger. About the time I figured out what was causing the interference they moved the horses to another pasture an turned off the fence. I shouldnt have any more problems, the farm was sold and they are buiilding houses there.

Jimmie

That certainly could be. We're a bunch of
mini-ranches with plenty of horses and
hot wires.

Thanks Jimmie.

I've just been out RF sniffing around the outside
of my house with the MFJ meter.

Seems my rain gutters give off some RF at
about 30MHz.

I've also got a metal shed that's not connected
to any power or anything else. It gives off
about 300-500 kHz from it's roof if I put the
meter on the roof. It's quiet on the sides
of the shed.

Sheesh. I'm drowning in incidental transmitters.

FWIW, I use 8lb monofiliament line and a 3oz fishing weight, and like others, cast it over the tree with a fishing pole. Wristrockets can't compare.

Also, in response to another poster, I have never had a fishing weight wrap around a tree branch as long as it is allowed to fall to the earth. In other words, allow the line to freely flow out until the weight has dropped to the ground.

Well my Antenna Im trying to raise and replace the rope is STUCK.

It seems after all this time the tree has trapped the rope up there,
and the antenna is Too high for me to
reach the rope with my Tree Trimmer on a ladder (its 20ft long)

SOOO, how does one get the rope to break or what can i pull up with a
rope if I toss it over the old rope to cut the line

(Ive already pulled as hard as I dare, its STUCK)

Sheesh Simple antenna projects never seem to be simple

I made a vertical colinear antenna using 6m (18 foot) of 50mm Dia (4") PVC tube. When vertical it is Ok, BUT it has two drawbacks:

1 - It bends when the wind blows
2 - It bends when the sun shines, bends away from the sun.

The "cure" is to put a 12" across X piece at the midle of it, then thread 4 nylon fishing lines from end-to-end, so the line is fastened to each end and one leg of the X. This is the "ships mast principle" for stopping a flexible mast bending.

You said yo want to use 2" diameter, and 7 metre lengths (20 foot). Sounds like you will have a worse problem than me. There is no reason why you cannot have three of these Xs along the length of the tube so that they overlap. See the drawing at:

http://web.telia.com/~u85920178/antennas/7db-colinear_9-shipsmast.gif

Hope this helps. Regards H

Forget about coax. too expensive, too heavy even if it would work.
With Loops you can zig zig in and out to get all the wire up it does
not need to be in a square etc. Just get it all up and it will work.
Why not a dipole which also can be bent. Try to avoil loading coils
if at all possible.

A rule of thumb that I developed by trial and error is
that the height limit for a PVC support or vertical is
about 20 feet. After wasting a lot of time trying to
go higher, I switched to 2x4s.

We live on a small suburban ranch. We have elec
fences as do some neighbors. Ours is off for testing.
I'm not sure what a furnace is. It's 100 degrees this week
(unseasonably low) in Phoenix..;-)

After sniffing around with the MFJ, and finding
my rain gutters seem to be resonating at about 30Mhz
I moved my dipole a bit so that the coax doesn't
cross the gutters. Now the coax goes from top of
mast to ground, and gets buried under about an
inch of sand on our beach. Previously all of
the coax was suspended above physical ground.

The click seems to be gone.

Perhaps the gutters were receiving neighborhood
clicks and rebroadcasting them into my coax.

Hmmm...30 MHz gutters...Maybe I'll work some
10 meters.

I built the QE-19 from the same site Tim mentioned. The "air valve"
for it is off-the-shelf so it's a plug-n-play project. It beats every
fishing rod, bow & arrow, sling shot..... anything I've ever tried
before. Beats them hands down. It'll easily clear a 100 foot height
and is accurate after you shoot it a couple times. It's a little
pricey but that could be spread out if it were to become a club
project.

My impression is that the CSV19, with its modified sprinkler valve, has a higher muzzle velocity than the QE-19. But overall, I agree 100%, that for me the tennis ball launcher was far and away the best choice.

I have some friends who are very good with crossbows and they tell me that I'm wrong, that the crossbow will do the job more reliably and accurately than my tennis ball cannon, but I don't have a crossbow and don't really intend to learn how to use one. I don't really want to shoot arrows into my neighbor's property either. The tennis ball cannon just made the job so easy, and literally the only gotcha is that you'll not only send the ball over the target tree, but probably the trees behind it if you aren't careful. One trick I learned very quickly: When you see the ball go over the target tree, grab the fishing line and stop it, then let it go so the ball can just fall from there. My trees are at the very edges/corners of my property, and using this trick I was able to ensure that the support lines are also within the property.

Hi Gents,

Just to give you some heads up on the good old cobweb, I have manufactured a mobile cobweb which I can only say works fantastic, but I did assemble it to a very logical plan so not to cause any SWR issues.

The first think I undertook after manufacturing the general cross shape which is mounted on a 300mm x 12mm thick aluminium plate was to start with 20m and only with a SWR meter shorten the length to the SWR was 1:1 on 14.200; this gave about a 3” gap at the ends. Unlike other cobwebs I terminated with an inline yellow crimp and joint them with 4 mm diameter nylon air pipe.

Remove the 20m wires and repeat the same with each band as above once they are all good connect up all the wires in the junction box and go to the datum frequencies and check again, they should all be the same.

Reference changing SWR when I first assembled the cobweb and tested it I undertook this at my factory which happened to be of the metal clad construction, although I was in the yard and about 10m away this caused lots of changes to the SWR, once I was well away from the buildings it was spot on.

This antenna works will for me as I ma 100% mobile it sits about 5m from the ground and seems to excel when near the sea, so I seem to spend most of my DXing time at the local beach.

Cheers

Climb up a ladder, cut it as high as you can.

The tree-trimmer-on-a-pole doohinkeys don't work well at all for
cutting ropes.

Next time use black ropes, they stand out a lot less than those
fluorescent orange ones!

Tim.

I've shot over 100 feet high with a Wrist Rocket using a 2 oz weight and about 6 pound test fishing line.

Make sure your fishing reel is nearly full, to minimize the resistance as the line comes off.

If you're using an asymmetrical dipole, the feedline is very likely a part of the antenna. So the source of the noise or the conductor which is radiating it might be closer to the antenna than you think.

If the rope is stationery, but the tree is growing, it will engulf the
rope. Not much you can do. I have a rope, a wire fence and some
twinlead standoffs that have all been swallowed up by various trees.
Best to leave a little slack.

A lead weight from a slingshot or an arrow from a bow will clear most anything if the string is set up correctly. But both are fairly dangerous coming down if the string breaks. That's the good thing about the tennis ball cannons, I think they're safer.

I chose the QE-19 because the components were off-the-shelf and required no modification.

I use a balun to hopefully decouple.
I got a little reduced click when I
brought the coax to physical ground
at the base of the mast, instead of
letting it run across the roof.

Today I experimented more. Seems the
click wants to appear when I get one
leg of the dipole within about 15 ft
of my phone/cable digital box on the
side of the house.

Everyone seems to assume this is local RFI - but I've heard something very like this recently - in the UK (I guess you're in US?). It's not electric fences or heating igniters - I am pretty familiar with what they sound like ....

I can't remember the exact time or frequency, but 20m is probable. I clearly remember that it wasn't on other bands, and it was in groups of 1Hz pulses, with quiet spells.

My guess is it could be some sort of OTH radar. I often hear OTHR pulses in the UK, but at a higher PRF. These are usually assumed to originate from the Cyprus or Middle East area.

Sometimes two pieces of metal tapping together in the wind can cause it.
I had put up a slopper for 20 meter coming of the top of my 50ft tower. When I put up the antenna I used a short piece of wire from the top of the tower to an insulator then connected the end of the antenna to the insulator leaving about a foot or so of the antenna sticking out of the insulator for prunning.
Well, thats as far as I ever got with the sloper, as a matter of fact I put ham radio aside for quiet a while but I still enjoyed listening for BCB dx once in a while. I begin to notice that sometimes I would start hearing clicks while listening to AM and it turned out the noise was caused by the tail I left on the 20M antenna that was hitting the tower.

4869. Why is my dipole low impedance?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-05-20 17:51:26 UTC
From: Lumpy <lumpy@digitalcartography.com>
Message-ID: <69gheqF329ik5U1@mid.individual.net>
Source record: 25491

I'm a little stumped.
I'm sure I'm missing something obvious
but I just can't see it.

Built a 40m wire dipole, 33ft per side, symmetrical.
Center mounted on an 18' pole. Ends of the
legs drop about 2 ft to 16' above ground.
Slack/dip in the wire legs is pretty minimal.
The mechanical connections of my antenna allow
me to get it pretty tight.

Without any balun, running coax to the center
feed point of the dipole, I get an impedance
of around 6-7 ohms.

Different lengths of coax, different pieces of coax,
make no difference. All the coax pieces I've
tried test ok for shorts and continuity. Two
of the test coax pieces are brand new.

Dipole legs aren't touching anything, including
each other. Nearest piece of metal is at least
a half wave away from the end of one leg.

Mast is an aluminum tubing tripod in sections.
The sections aren't particularly bonded, the
section connectors are plastic/nylon. The
telescopic sections of the tripod/mast are
4' long each. The mast has rubber feet on
it's tripod legs, it is not bonded to earth.

Same 6-7 ohms shows up on the MFJ meter whether
the mast is at 10 ft or 18 ft.

Same 6-7 ohms shows up whether I stand at
the base of the mast with a 17' piece of
coax attached, or if I add a 50 or 100 ft
length of coax and stand virtually anywhere.

Why isn't my dipole showing a more expectable
impedance? Any guesses?

When I lived in AZ, my neighbor had an electric fence
that was no bother except when it was windy. It was
a fabric fence woven with embedded conductors. There
was a piece about 10 inches long at the knot at the
end that shorted out to the pole when the wind blew.
Snipping it off cured the problem.

Silly question - have you calibrated your MFJ meter against a known-good load recently?

The fact that you get the same impedance reading when you add 50 feet of coax (which is pretty close to a quarter-wavelength) is a red flag. Since the added cable is roughly 1/4 wavelength, you'd expect to see a *big* impedance transformation - a load of 6 ohms at one end, would be transformed up to around 450 ohms at the other end.

Since you're getting the same reading with, and without the quarter-wavelength cable extension, I'd be very prone to suspect that your measurement tool (the MFJ meter) is frotzed.

The MFJ-259 and -269 meters use "zero bias" Schottky diodes as part of their power-measurement circuitry. These diodes are relatively delicate, and can be damaged if the meter inputs are exposed to more than a relatively small amount of RF. Even keying up a transmitter on one antenna, while having the meter hooked to another (nearby) antenna at the same time, can hit the diodes with a high enough voltage to pop 'em. Reportedly, the -269 meter can also be damaged if you turn the UHF feature on or off at the wrong time or with the controls in the wrong settings.

Check your meter with several loads - a 50-ohm dummy load, 25- and 100-ohm test loads, open circuit, and short circuit. See whether it reads close to the correct value or not.

Plain resistors read appropriately.
27ohms, 56 ohms etc.

I don't have a good dummy load. I have a 50 ohm
50w resistor but it's wire wound. It varies all
over the range when I sweep the MFJ.

Known good piece of coax, end shorted or open,
reads 50 ohms when the MFJ is tuned to the quarter
wave of the coax.

MFJ seems to read a vertical hamstick
appropriately -

http://digitalcartography.com/n0eq/MFJswitchDetail-600x400.jpg

I just made a contact on 5W QRP from Phoenix (here)
to St Louis. So I have to guess the antenna isn't
open or shorted or something else catastrophic.
That's through an LDG tuner.

But -

Running the dipole into my Yaesu 857 with external
tuner bypassed, shows an SWR high enough to cause
the transciever to self protect shut down.

Engage the tuner, SWR comes down to 1.5:1, and
I'm putting out (at least to the back of the radio)
very close to the selected 5 watts.

Something's seriously wrong there. A shorted quarter wavelength of coax should read very high impedance when the far end is shorted and very low when the far end is open. The only time it should read 50 ohms with the far end shorted or open is if it has many dB of loss. And no even half decent coax should have anywhere near that much loss in a quarter wavelength.

So it appears that either your coax is extremely lossy for some reason (and I can't think of any mechanism which would cause that much loss unless the coax is specifically designed to be very lossy for some special reason) or the meter is oscillating or otherwise misbehaving when connected to coax.

> I'm a little stumped.
> I'm sure I'm missing something obvious
> but I just can't see it.

Stupid questions:

1 - Are you using a short test jumper cable or adapter connector between the test instrument and the end of the coax? Could the test lead or connector be at fault?

2 - Is there any possibility of a STRONG signal coming back down the cable to stuff up your test instrument readings? Do you live near a source of RF, such as local broadcast radio?

3 - Is there any possibility both feeder cables are defective? Perhaps you are using coaxial cable not meant for this purpose? TV coax, or LAN cable?

4 - Have you wiped out your neighbours TV viewing or something? Checked the cables for sabotage (pins or nails)?

5 - Have you climbed the mast and checked the antenna directly at the feed point, without a feeder cable?

You have probably thought of all these, but I had to ask. Regards Harry

At this point, I think I'd set aside the MFJ and resort to a VSWR meter.
Once you verify the antenna, you can get to checking out the MFJ. The front
end bridge is very sensitive to overload and damages easily.

Maybe I'm not testing correctly.
100' length of new coax. Tests ok for no shorts or open.

MFJ set to 2.4MHz gives me a Z (on the advanced
menu) of 50 ohms with distal end of the coax
either open or shorted. Actually shorting the
end with a screwdriver shaft drops the Z from
50 to 49. I assume 1 ohm is within normal limits.

Same settings gives me an R (on the main menu)
of zero ohms either open or shorted.

I get exactly the same results on several
pieces of coax, old/new, RG8 or 58. Resistance
is zero, impedance is 50, shorted or open at
the resonant quarter freq.

4883. 75m/30m, 40m/17m Dual Banders

Newsgroup: rec.radio.amateur.antenna
Date: 2008-05-20 21:51:31 UTC
From: Cecil Moore <nospam@w5dxp.com>
Message-ID: <DJHYj.86$ui2.72@nlpi069.nbdc.sbc.com>
Source record: 25405

There was a discussion the other day about stub loaded dipoles. A 30m dipole loaded at each end with a 30m/4 shorted stub is resonant on both 30m and 75m. A 17m dipole loaded at each end with a 17m/4 shorted stub is resonant on both 17m and 40m. The stubs provide inductive loading on the lower bands resulting in "shorty" dipoles, shrunk by about 20%.

I've summarized two such antennas on my web site at:

http://www.w5dxp.com/dualband.gif

Hi Lumpy

I really like your music. You do a terriffic job with that guitar.
I'd suggest that you'd do yourself a favor if you recognize that the input impedance of your antenna is not being measured properly by your meter. Instead, try to think of something that is causing the meter to read improperly.
Could the error be introduced by a stray (off frequency) signal effecting the meter movement? You know, the antenna picks up the signal and introduces an error.
Remember how the impedance looking into a length of coax, that is either opened or shorted, varies all over the place when the length is uncontrolled.. The only time it's impedance is equal to it's Zo is when it's length is 1/8th wave (or odd multiples). And, then, the impedance is very nearly purely reactancive.

At 2.4 MHz, the line is pretty close to 3/8 wavelength, not 1/4 -- assuming it has solid and not foamed dielectric. At that length with the other end shorted or open, the impedance would be very nearly 50 ohms, all reactive, which means the resistance would be zero as you're seeing. So those measurements are correct. Your meter is showing the correct values when measuring resistors (purely resistive) and the shorted/open coax (purely reactive), so there's nothing obviously wrong with the meter.

The remaining possibility for your problem with the antenna is external RF, as someone else mentioned earlier. I find it nearly impossible to use my 259B for antenna measurements at my QTH because of strong AM, FM, and TV signals -- ironically, the "antenna analyzer" is great for a lot of other chores, but not for actually analyzing antennas. It's pretty likely that's what your problem is too. When measuring antennas, I have to use filters which introduce minimal impedance disturbances at the

measurement frequency while providing attenuation of the offending signals.

If I look in the antenna books, the feedpoint impedance of a half-wave dipole less than 0.1 wavelengths above a perfect ground can be less than 10 ohms.

You are, say, 17 feet above ground. That's more like 0.14 wavelengths, and the charts in the antenna handbooks show that as you get up to 0.2 or 0.3 wavelengths that you'd expect to be way above ten ohms. And your ground I'm assuming is not "perfect", with a zero-area call it might be better than average, but it's probably not salt-water.

So maybe the numbers don't add up perfectly to match the charts in the books, but I think the lesson is that a very low dipole (you're just "pretty low") dipole over perfect ground (maybe you're "very good") can have a very low feedpoint impedance, less than 10 ohms in some circumstances.

If your ground really is that good, you're a prime candidate for verticals or an array of verticals. I used to live in the midwest next to the Mississippi, and the ground conductivity was really very very good (if not as good as saltwater) and I was very happy with my 4BTV's performance.

Tim.

more relevant is the 2ad=v^2 equation... height goes as the square of the launch velocity, neglecting air drag and line drag.

but, where the bow and arrow really excel is in the overall larger mass of the projectile and higher launch energy (mostly the latter. the arrow is a couple or three ounces.. same as the wrist rocket.. but the bow will easily have a 50 lb draw and longer distance.

See, e.g., http://www.stortford-archers.org.uk/medieval.htm for some discussion of bow and arrow physics

A very important point. In many areas, firing a crossbow (which is
generally perceived as a lethal weapon) at anything other than a
designated target would set you up for a lot of hassles with the local
constabulary, or worse. The tennis ball launcher (avoid the "cannon"
term..) looks less "weapon-y"

Not that shoulder fired one that everyone's
been looking at..:-)
http://www.antennalaunchers.com/antlaunching.html

It looks like an RPG. Wander around aiming that
thing at the top of your trees while the
gendarmerie rides past and I'll bet you'll
be asked to "DO IT NOW".

Hi Cecil, How do you model the 1/4wl 3" stubs on the ends of the dipole? I have EZNEC 4.0.

Hi Al W6LX, et. al. --

I bought a 'real' EZ HANG from Dennis (KG4ETM) at Dayton,
(<http://ezhang.com>) and after taking a few trial shots
I had *no* problem shooting the one ounce weight over a
135+ foot Tulip Poplar tree in my back yard in northern
Virginia.

The tree was so tall that I used -all- 300 feet of the
monofilament line and the weight ended up about three feet
off the ground.

My point is that if you use an "EZ Hang" (or a counterfeit)
properly, that thing really works!

Wish you were closer so I could show you. It's a great
gadget!

Another way of getting a loop antenna for 80m for reduced place is
switching two 40m delta loops in serie.

This website is in German language shows some drawings with a 41 feet
mast in the middle and four 10 feet supports in square.
It was published in a standard antenna book in Germany from Karl
Rothammel, DM2ABK.

http://www.technik.ba-ravensburg.de/~lau/drahtpyramide.htm

"The WBï¿½AOF 80 meter pyramid antenna" may be known in the USA.

Source record: 25428

http://www.syubrawi.com/skin-care-supplies ,Serious skin care starts with a serious regimen that you follow morning, noon and night. If you don't want to have a leathery and wrinkly face by the time you're thirty, I suggest that you use a good facial moisturizer every morning with at least a sun protection factor (SPF) of 15. Since the majority of skin damage is a direct result of unprotected sun exposure, make sure you're always covered with enough SPF to remain wrinkle free. Surprisingly enough, most of the sun you get isn't on days when you're outside enjoying a BBQ or playing frisbee. Instead, most of it is caused by incidental exposure. This means you get sun spots from the rays you catch taking the groceries to your car, checking the mail and walking the dog.

Besides a good moisturizer with an SPF of 15 or more, serious skin care also includes a good cleanser. Make sure you wash the old make up and oil accumulated throughout the day off each night, then again in the morning. This will cut down on clogged and enlarged pores. There's nothing more unattractive than a person whose pores are bigger than my studio apartment. A huge reason to avoid enlarged pores is the fact that once they're enlarged, there's nothing you can do to shrink them down. If your pores are big now, the only thing you can do is try to keep them from getting bigger.

Another thing you should do is exfoliate. Serious skin care means sloughing off dead skin cells that make your face look dull and flaky. This also helps remove the cells that can clog your pores and lead to pimples. If you have other questions about serious skin care, hop online and check out some message boards for tips and tricks. If you can't find anything there, you can always rely on the beauty magazines on newsstands.

I guess you can put this crap on the jackets of the wire antennas to keep
them from being exposed to UV!!

4909. antenna construction

Newsgroup: rec.radio.amateur.antenna
Date: 2008-05-22 15:32:26 UTC
From: W3CQH <hsgorden@comcast.net>
Message-ID: <_s6dnZtVn5WOD6jVnZ2dnUVZ_szinZ2d@comcast.com>
Source record: 25431

I have the following represents my roof and the tree in my backyard.

The length of the roof is 90ft, it is 15ft from the center line to each edge, (roughly 30ft),
height of roof is approx 22ft at the peak and 10ft at the gutter edge..

The tree is approximately 35ft high.

```
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
x
O x
x
x
x ----------------------------------------------------x
x
x
xxxxxxxxxx x
O x
x x
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
x O x
x x
xxxxxxxxxx
TREE
```

My question is: do you think it would be better to run a configuration as say a Windom from the tree to the points on the roof (the points can be moved) or just a simple inverted "V" and the angle of the "V" in any case is going to be very narrow. I would be feeding either one via some Rg8x approximately 65ft.

I would like to be able to use the ant from 160m - 6m if possible, I will be feeding it via a tuner, and the wire is going to be #26 enameled as it can't be seen.

Comments please.

Guess I'll reply to this one! ;^)

How much total length will you have? A Windom for 160 needs > 260 feet. I used a windom for a while because it was convenient, the short leg dropped the coax directly down to my shack window. The antenna performed okay. Depending on your lot size, you might not be able to run a full 160 meter version. would 80 meters be an okay bottom limit? Even if you had to let the ends drop a bit, though tuning (short vs long leg) will be a little different.

Inverted v might also be a little difficult. You might want to go for a plain dipole.

I'm pretty dense today - getting over a nasty head cold, so I'm going to ask a few questions.

You just have the one tree?

If so, where are you planning to hang the other end of the dipole. Certainly an inverted V is going to need something in the middle.

With the tree at 35 feet, what is the maximum height you can hang a wire at?

It doesn't sound like a real optimum site, but don't worry, we can get you something that will work okay.

It might be easier to do what I did. I have 17 and 40 meter dipoles
connected to a common feedpoint. The 17 m dipole is the supporting element,
hung between two trees at about 50 feet. The 40 m dipole is arranged as an
inverted V. The trees are not far enough apart to have the 40 m dipole on
top. Either way, the 40 m has to be resonated first.

4919. Sunspot cycle more dud than radiation flood

Newsgroup: rec.radio.amateur.antenna
Date: 2008-05-23 06:07:06 UTC

Sunspot cycle more dud than radiation flood

By Dan Sorenson
ARIZONA DAILY STAR

Many solar scientists expected the new sunspot cycle to be a whopper, a prolonged solar tantrum that could fry satellites and raise hell with earthly communications, the power grid and modern electronics.
But there's scant proof Sunspot Cycle 24 is even here, let alone the debut of big trouble.
So far there have been just a couple minor zits on the face of the sun to suggest the old cycle is over and the new one is coming.
The roughly 11-year cycle of sunspot activity should have bottomed out last year, the end of Cycle 23 and the beginning of Cycle 24. That would have put the peak in new sunspot activity around 2012.
But a dud sunspot cycle would not necessarily make it a boring period, especially for two solar scientists with the Tucson-based National Solar Observatory.
Two years ago, William Livingston and Matt Penn wrote a paper for the journal Science predicting that this could not only be a dud sunspot cycle, but the start of another extended down period in solar activity. It was based on their analysis of weakening sunspot intensity and said sunspots might vanish by 2015.
And here's the punch line: That last long-term down period, 1645-1715, coincided with the Little Ice Age, a period of bitter cold winters.
That kind of talk could ruffle some feathers in this time of climate change and global warming, starring man-made carbon dioxide as the devil.
The paper, rejected in peer review, was never published by Science.
Livingston said he's OK with the rejection.
"I accept what the reviewers said," Livingston said. "'If you are going to make such statement, you had better have strong evidence.' "
Livingston said their projections were based on observations of a trend in decreasingly powerful sunspots but reviewers felt it was merely a statistical argument.
He is aware that some opponents of the prevailing position that climate change and global warming are the result of manmade activity — greenhouse gas, specifically carbon dioxide, buildup — are very much interested in the idea that changes might be related to solar activity.
"But it has not been proven yet," cautioned Livingston, an astronomer emeritus who still works out of an office at the National Optical Astronomy Observatory headquarters building on the University of Arizona campus.
"We may have to wait. We may be wrong. (But) the sun is going to entertain us one way or another," he said.
It's not just a scientific curiosity. There's a lot at stake in predicting

whether sunspot cycles are going to be tame or wild, said Matt Penn of the National Solar Observatory.
The powerful blasts of radiation that come from solar activity can fry electronic equipment on Earth; particularly vulnerable are satellites.
The high-energy radiation produced by solar flares travels at near the speed of light, getting to Earth in just minutes.
But the magnetic effects of a solar flare can take between two and three days to reach Earth, said Penn, a solar scientist.
In the 1800s, magnetic blasts from intense solar activity induced currents in telegraph lines in the U.S. and Italy, starting fires and damaging equipment. Later, it was learned that solar activity affected radio transmission.
It can also affect the electrical-power grid. A solar tantrum in 1989 blew transformers and caused a blackout in Canada. And a number of satellites are thought to have failed from exposure to high-energy blasts from solar activity.
Satellite operators can turn them away or shut down vulnerable equipment aboard, and astronauts can use shielding to avoid those blasts.
If Cycle 24 is the big cycle predicted, Penn said, "it's likely we'll have geomagnetic storms with a lot of sunspots, a lot of flares on the sun."
Penn said even so-called "quiet sun" periods are far from boring because the sun's "surface consists of Texas-sized hot gas bubbles, which rise upward at a speed of about a mile per second. The gas cools and falls downward in narrower channels at about the same speed. That's what we call the 'quiet sun.'"
"As we get more into the space environment with satellites, GPS and communication satellites, it means money. People who are about to launch new communication satellites really want to know how much shielding to put on their satellites.
"But shielding amounts to weight, which is money. If they want them to last through (an intense cycle), they're going to want to protect them more, and that will cost them more."
Penn is the telescope scientist on the McMath-Pierce solar telescope, the strange angular white thing amid all the white and silver-domed things atop Kitt Peak. Specifically, Penn works with an instrument that "sees" in the infrared range to provide information about magnetic activity.
Sometimes, sunspot activity is more than theory or data to him.
Several years ago, he was making an early-morning run from Tucson up to Kitt Peak to do some solar observing. He noticed his gas gauge was dangerously low and decided to stop for gas at the convenience store in Three Points.
It was about 5 a.m., and no one was there to take cash, so he tried to use his credit card to gas up. But the pay-at-the-pump system was down.
Crossing his fingers and driving up the mountain, Penn said he hoped he'd have enough gas after work to make it back to the station on the way home.
When he got to work, he learned that "a communications satellite had been damaged by (a solar flare). Lots of communications were dropped that morning, and my credit-card pay-at-the-pump attempt was one of them."
Though Aimee Norton appreciates the practical benefits of being able to predict the sun's activity, solving some of the star's mysteries that

relate to the big picture are more compelling. Norton is a program scientist on the solar observatory's SOLIS (Synoptic Optical Long-term Investigations of the Sun) facility at Kitt Peak.

"Part of what we're trying to understand is how the magnetic field regulates or moderates the energy that is transported in the atmosphere," Norton said. "Because one of the mysteries of the sun is, it's hotter in the upper atmosphere than (at the surface). So there is energy being transported. Some people think the magnetic field is somehow magically getting that energy out there."

Norton said she's hoping for a powerful cycle, noting, "It would give us more things to do research with — either that or no cycle at all, which would be similar to the Maunder Minimum."

She said she figures there's little chance of a completely dead cycle but added, "Wouldn't that be fascinating if the solar system managed to offset our contribution?"

Just some thoughts...

That #26 wire is going to be a problem no matter what type antenna you end up with. For the longer antennas, HF, etc, it's strength is going to be sort of limiting. It is sort of difficult to see, but it's far from being invisible. So, if you are in one of 'those' neighborhoods that don't like 'visible' antennas there is another choice instead of an invisible antenna. That's using something that is very visible, but not normally associated with antennas. The first thing that comes to mind is a flag pole. Certainly 'do-able', and certainly not going to be 'simple' if it covers more than one 'chunk' of HF. The 'simple' way of 'curing' that sort of thingy is to throw money at it, to some ridiculous point. (Wonder how 'they'ed feel about a 'commemorative' Atlas missile monument in your yard?)

I think you might do some thinking about what's the longest, sort of straight, 'run' you can manage using the roof ridge and tree. A few 'bends' in that 'straight' run are allowable, sort of. And then consider various ways of 'loading' that run. One option might be a 'short' but 'long' inverted 'L', a "lazy-L"? Not exactly the best, has it's own set of 'problems', but if it works, who cares...much. Having 'been there, done that' at at one time or another, I really wish you luck.

A 22' flagpole (with buried radials) can be base-fed
with an SG-230 (for instance) to achieve reasonable
performance on 40m-10m.

Good grief, the new sunspot cycle has barely begun. Give it a little time.
It is way too soon to expect any fireworks, even in an exceptional solar
cycle.

I used one of those for several years in a "restricted" neighborhood.
Performance was not bad. I used a manually switched coil/capacitor
combination mounted at the base in a wooden box obtained from the local
beekeeper supply house. While the box was a little large, it was
inexpensive, and held up well in weather with a new paint job every 2-3
years.

Thanks for your thoughts - I am NOT allowed either of the 2 items that you suggested (flag pole or missile - although I would like to have a Gatling Gun mounted and take pot shots at the senior citizens that use my street as a tune up for drag racing).

1] In my current configuration I have a #13ga jacketed wire coming out of a Icom A4 auto- tuner (which is in the attic next to the vent window). From the tuner, it goes up about 3 feet to the roof peak, makes a 90 degree turn and then traverses down the edge (15ft) to make a 90 degree turn down to the end of the roof (90ft) running along each of the gutters sides (but actual on the roof). Then it makes another 90 degree turn and goes up and over the peak to the other side of the roof, about (30ft) and makes another 90 degree turn and comes back (90ft) turns back up to the peak (15ft) and back down to the ground side of the tuner.

I am hearing a lot of sigs, but I am having probs being heard! 100w!

2] Before I had this configuration, it was basically the same, except the auto-tuner wasn't in line, instead I was using a manual tuner. I had the same configuration on the roof, and an additional 2 runs (LOOPS) of the same size wire inside of the attic, total length of approximately 540ft. It was working (80-10), but I couldn't get it to tune to 160m. On the VHF/UHF frequencies, 6m thru 70cm it was working as a multi-wavelength RHOMBIC. I was able to work a bunch more stations, but still I thought I wanted more.

But the problem is that the outside portion - the signals being transmitted - that the roof was probably absorbing most of them.

3] Whether I use a manual or auto tuner, I am trying to get the best configuration other laying the wire on the roof or stringing it along the rafters in the attic.

The distance is approximately 20 feet from the tree to the house. I can bury a piece of coax from the house to the tree, and then run it up the tree to a center connection for a dipole, but the arms of the dipole are going to have to be bent into a "V" and terminate at some point along the longest sides of the roof just above the gutters.

4] As you suggested, I could run a dipole (using more of the #13ga wire, the ends facing N/S) along the ridge line and center or off-center feed it with coax, but then again, it will be laying on the roof. (90ft straight ridge line).

73's

A not 'too' visible antenna ,which might not be recognised as an antenna
is a loop around the house (provided you live in a detached house).
At gutter level at the corners you could fit say 1 foot long 1 inch
plastic pipe pointing sidewards or under a suitable angle.
Each pipe end has a saw cut to accept the antenna wire which can be
sealed with epoxy glue or a piece of tape.
Use a twin wire feeder and a suitable matching unit (tuner ,if you
prefer that word). The loop should work well for all wave lengths
equal or smaller the the loop circumference .

While on a 2 months' visit to the LA area (Torrance) I managed to put
up such a loop ,extended to the end of the garden making it a full wave
length for 75 metres. In spite of being only 10 ft off the ground
(probably making it a NVIS antenna) I comfortably worked the Sacramento
area.
Such a loop is definetely worth a try.

Good lord, what kind of neighborhood won't allow a flagpole?
Unpatriotic creeps? Sounds like you need to get PRB-1 in your corner.
Essentially, they cannot stop you from erecting *something*, you have
the right to an antenna. You might not get something really great, but
they will need to accomodate to some extent. A flagpole antenna is one
of those compromises.

I routinely work anywhere CONUS from Phoenix
on 5w into either a screwdriver vertical,
a hamstick vertical or a pair of hamsticks
horizontal dipole. With those same antennas
and 100w I can work Australia and Latin America.

Mount a hamstick or screwdriver on your car
and run a length of RG58 inside to your transciever.

I think you describe having 90' of roofline.
That's enough for a good sized wire dipole.

Bird feeders, security cameras and windsocks
for some reason seem to work best at 16.6' off the ground.

Well, I'm not ready to give up my internal combustion engines just yet.
Neither side has convincing arguments as far as I'm concerned. And I do not
trust the global warming folks at all, since most of their claims are
unprovable and I suspect their leaders' political motives.

The real answer to global warming, assuming it exists and assuming that we
are causing it, is a severe population reduction. Any volunteers?

I didn't think so...<G>

A "planned" community, with a strict set of CC&Rs, enforced by a homeowner's association whose board has an extremely anal attitude towards any variation at all in the community's planned appearance scheme?

> Sounds like you need to get PRB-1 in your corner.
>Essentially, they cannot stop you from erecting *something*, you have
>the right to an antenna.

PRB-1 applies only to governmental restrictions (e.g. city and county zoning rules).

Unfortunately, it does not apply to CC&Rs (codes, covenants, and restrictions) which are written into the title of a home or other piece of property. Legally, these are part of the contract of sale of the property - they're a private agreement between seller and buyer, and are not implemented or enforced by the local government.

Hams have asked the FCC to rule that PRB-1 overrides such CC&Rs. The FCC has declined to do so, on the grounds that it doesn't have the legal authority - Congress *could* have written/extended PRB-1 to override such CC&Rs, but chose not to do so.

See http://www.eham.net/articles/16368 for one story on this aspect of the problem.

Unfortunately for hams, antenna-restrictive CC&Rs are quite common in newer communities and are becoming even more so. I've heard that in some areas, they're almost (but not quite) a legal fact-of-life, in that lenders won't provide financing for the construction of the community in the first place unless the builder includes a fairly stiff set of CC&Rs in the plans (to "preserve the aesthetics and value of the community" I suppose).

I believe I read an article a few months ago about legislation which specifically overrides CC&Rs to the extent of allowing the flying of a United States flag, but I can't recall the details... and I don't think it would necessarily have allowed a long vertical flagpole.

There *is* one possible "out" with regard to antennas and CC&Rs, although it does not involve PRB-1. Instead, it uses the OTARD (Over-The-Air Reception Devices) rule (47 C.F.R. Section 1.4000), which specifically allows the installation of television, direct-broadcast-satellite, and "fixed wireless" antennas. This rule *does* override CC&R restrictions, as well as local zoning restrictions.

It's not unlimited - mast height is limited to 12 feet, dish size is limited to 1 metre, the override applies only to antennas installed in an "exclusive use" part of the property (i.e. not in shared areas), and there can be *some* restrictions on placement in limited cases. In general, though, you're allowed to put up a TV antenna, and cannot be hit with restrictions which materially increase your costs in doing so or make the job significantly more difficult.

The rule doesn't apply to ham antennas. However, there's at least one company (Force 12, I believe), which makes an antenna that can serve a dual purpose - it's a shortened, center-fed-and-loaded (I think) HF vertical, and also can serve as a TV reception antenna.

Another possible option would be to put up an *insulated* 12-foot mast pipe with a standard TV log-periodic antenna at the top, run a set of radials along the roof, and feed it at the base with an antenna tuner. You might add some switchable base-loading coils, or even figure out some way to relay-jumper the log-periodic at the top to the mast so that it acts as a capacity hat.

As long as you *do* use the antenna for TV reception, I believe it'd be covered by the OTARD preemption, even if you also use it occasionally for ham-band use. [Just remember to disconnect the TV feed system before keying up!!!]

See http://www.fcc.gov/mb/facts/otard.html for details.

Time to find a different place to live in. I live in a modern
development in which the only restrictions are that you keep the house
presentable, and the lawn mowed. There are some restrictions on tower
height and fall radius, but I could put one up.

Homeowners association = evil, bad, ptui!

Right there is the first clue that people shouldn't even consider living
in a neighborhood.

Really, there are other options.

You are quite possibly correct, Cecil, Interrupting/changing the flow of ocean currents could indeed have an effect on certain things such as the Gulf stream. There are plausable scenarios that even in a warming environment, interruption of the gulf stream could cause the British Isles to become a lot colder, as much of their temperate climate depends on that Gulf stream moderating their high latitude temps.

So in any event, hot or cold, we could ber causing the problem! ;^)

Smart man, Ed. Listen to the science, not the politicians. When I see
people lining up by party, I tend to discount the politics.

But there is some science here that is fact. The rest is pretty
compelling. What is needed is the disbelievers to come up with equally
valid science to show why the fist fact is being negated.

That is all I ask - No Algore insults or whatever the leeburuls do to
make fun of the other side. Kind of like Moore's law, first person that
brings politics into it loses.

hmmm Coslo's law?? My chance at netnews immortality.... 8^)

> The real answer to global warming, assuming it exists and assuming that we
> are causing it, is a severe population reduction. Any volunteers?

If I may be so gloomy, Ed, I think Mother Nature is very close to a
self correcting move in that direction. I suspect a global famine in the
not too distant future. In some parts of the world, rice is now costing
more that we pay for beef.

Buy Febreeze stock........

Whatever it is that we are doing, the Martians are
doing the same thing. The melting of the polar
ice cap on Mars is very closely correlated to
the melting of the polar ice cap on Earth.

Seriously, one can see from the temperature graph
history that the temperature was almost 5 degrees F
hotter 130,000 and 325,000 years ago than it is today.
In fact, close examination of the temperature graph
shows that the *average* temperature peaked 8000
years ago and has been falling ever since.

Did you know that Al Gore used computer generated
graphics from "The Day After Tomorrow" for his movie?
Did he think no one would notice? Do you reckon that
is indeed an inconvenient truth?

> Yup. Kind of hard to refute the geological data on that one.

Only it isn't the CO2 level triggering the ice age, it is one of the
effects of that warming brought about by the increased CO2.

We have to be careful of going into a pick and choose mode. It is
disingenuous at best to say that CO2 warming doesn't exist. But it
causes global cooling.

Heck if it does, that will be one whole awful lot worse than global
warming. Glaciers don't support a whole lot of life..

Now onto that data.

The present interglacial is a tad cooler than some of the others (note
they say "at this site". That is important because it's a big world.
It's been a miserable cold spring here in Pennsylvania. That doesn't
mean it's been miserable and cold everywhere else.

So here we have an apparent cycle.

Is there a reason to attach more credence to benthic foraminfera than to
CO@ heat retention? (I believe it is fairly compelling, but I'm not
arguing against the point.

Isn't that 5 Million year plot interesting?

Which all brings up one of the most frustrating parts of the GW debate.
The uncertainty. There is so much data coming in. We humans love to look

for patterns, so we tend to find them. Some of the things in those patterns may be involved, some may not. Certainly in that one plot, the temperatures have had an upward trend. Coupled with all that is the random factor. Suppose that a modern day version of the Deccan traps occurs. At that time, our contribution to atmospheric CO2 and other greenhouse gases will be moot.

http://en.wikipedia.org/wiki/Deccan_Traps

then we are really boinked.

I have here a second hand Motorola PD 1150 UHF antenna.
It is dump from the industry or goverment(450-460MHz) but the swr is also
very well in some parts of the70cm ham band?
This antenna is like new because it never used outsite.
It is a big white stick with 3 litle radials and on top a lighting security.
Have anyone the manual,specs or a link for this antenna?

Thanks SD.

Proctor and Gamble closed at $65.27 today. It paid $0.40 a share last quarter.

Hi Mike, speaking of things that are possible, it's possible that the hot air Al Gore produces has contributed more to global warming than anything else. Personally, I don't believe that. I think it's caused by the Sun.

Indeed! And the "Hockey Stick" has been shown to be bad data, and worse statistics. The "increasing frequency and intensity of hurricanes" has now been disproved by none other that the sources he quotes, as has his the claim concerning changes to the Mt. Kilimanjaro snow pack. All in nicely refereed papers in reputable journals.

I await the release of "An Inconvenient Truth II: Oops!" Not holding my breath, though.

So.. about 30 inches (based on the wrist rocket I have).. care to
guestimate how hard you're pulling? (maybe I can make some
measurements on my old wrist rocket..)

Again, *Remember I used safety glasses* in case a rubber
snapped. You need to do that.

I didn't measure anything. But, 30 inches sounds about right.
All I did was pull *really* hard on the rubbers and (using a
one-ounce weight as I described) the darned thing went up
like a rocket, up and over the tree.

It amazed me.

So, don't be afraid to pull the rubber bands 30+ inches.
Unless they're old, they won't snap.

Hi Dale,

I found a review from Radcom on the net and it sounds good.
http://www.mixw.co.uk/product/reviewAA200.htm
I sent an e-mail to the designer of the Analyser and he says it does not require re-calibration. After hearing that I was sold. I ordered mine last night.
He also sent me this link http://www.rigexpert.com/index?s=aa200&f=inside if you haven't seen it.

That feature is a two-edged sword. On the one hand, it means the analyser is immediately ready for routine measurements. That of course is a good feature for most of the users, most of the time.

On the other hand, if it doesn't have the *capability* to be recalibrated when different kinds of test fixtures are attached, it means that some useful kinds of measurements will not be possible... or worse, will appear to be possible but may give wrong answers. Measurements of the resonant frequencies of coaxial chokes are an example where analysers that cannot be recalibrated will give large errors - see the last few paragraphs of:
http://audiosystemsgroup.com/RFI-Ham.pdf

There's a place for both the simple handheld analysers and the ones that have more features but live on a bench. It's the buyer's choice... but whichever one you buy (or build) first, you may eventually find uses for both.

==========
In my situation as described above , I also had to deal with (earthed?)
metal gutters , but thanks to the 1 inch diam. plastic pipes at the
corners of the house ,keeping the antenna away from the gutter ,the
loop worked quite well (as an NVIS antenna).

not 'confuse' it, correlate it... there have been several studies that have correlated solar activity with global temperature changes. if we are indeed in a relatively active part of a long term solar fluctuation (hundreds of years not dozens) then does it not make sense that the solar activity may be warming us up?? Even other planets are being affected, read to the last line of the explanation of this pretty picture:
http://antwrp.gsfc.nasa.gov/apod/ap080523.html
Surely you can't blame human activity on global warming on Jupiter... even though we have dumped a bit of left over space debris in there recently.

Posted on behalf of WA2OQM whose newsgroups connection is interrupted. F8ND

The comments by the Hams in this group don't point out the fallacy for the Carbon target of the environmental commissars. Some have alluded to the enrichment of the elite of a Marxist State i.e. the political class. I for one would like to expose these charlatans by showing the errors in which they pick their data .

1 - C14 dating in the XX century to prove the anthropogenic cause of increased Carbon and not accounting for the proportional increase in C14 to nuclear explosions in the atmosphere ending up in the recent Ice cores of glaciers. Using the fixed proportion of C14 to non- isotopic carbon askew the Carbon concentrations.

2 - The disregard for the modulating and moderating effects of the Carbonic acid cycle and the Photosynthesis cycle on atmosphere CO2.

3- The disregard of the Methane sink in the upper atmosphere that is influenced on the catalytic action of U.V. and the geomagnetic activity of the Earth. methane is far more of a "greenhouse" gas than CO2. Geomagnetic changes bend shorter wavelength in varying ways and create changes in paths of shorter wave length solar radiation just as they do to radio frequency electromagnetic radiation we hams employ.

4 - Then there are the vagaries of Solar radiation and Sunspots and the 11 year Solar cycles which are poorly understood an have a know relationship to climatic variations.

The U.N. science consensus cleverly declares that all these factors are of little consequence to the "Anthropogenic" factor. Its hard for any rational person to accept this unless they are politically motivated. Please post this with my call on the News group.

There's a municipal airport, KSDL, about 2 miles
from me. Except for a very occasional tree, it's
line of sight.

Would a radar induced noise tend to attenuate
if my receiving antenna (dipole) were off axis
to the radar? Seems to me that it was indeed
stronger when the lobes pointed toward the
airport.

> Best regards, Richard Harrison, KB5WZI

I have one electronic clock (locked to WWV) that makes a QRM click every second when the second hand moves. Looking inside the clock, I've found a small coil of wire that was the mechanical actuator for the second hand. Placing a 100pf cap across the coil greatly reduced the noise.

Leave it to the lower-half of the IQ range to argue that dumping OVER 22
million tons of crap into the atmosphere a day would not have a long term
effect on our planet. Lucky for most of us that we'll be dead shortly
(20-40 years) and not have to worry about it.

Oh, your worried about brain-washing your kinds? Your a good parent!

The Earth's atmosphere is roughly 2.7X10^16 tons.

22 million tons is .000000039% of that, so at that rate it
would take a million years to get to .039% assuming it all stuck.

Just for added effect, when I made my tennis ball launcher I spray-painted it yellow and then added black stencils with BIOHAZARD and FALLOUT SHELTER symbology on. And then I stenciled BUTTERCUP on for the opposite impression :-).

I'm sure that some people are comfortable with lead weights flying through the air, or with crossbows. Me, I just happen (perhaps through lack of ability with the other two - I tried, but failed with slingshot and crossbow, but the tennis ball cannon worked the first time!) to be pefectly comfortable with the tennis ball cannon. And it worked, man it worked. I am so so so happy with the resulting antenna, 100 feet up between two trees.

Yes, it is well known scientific fact that the "more than
25 cubic kilometres of rock, ash, and pumice" ejected by
Krakatoa destroyed all life on this planet in 1883. (Compared
to Mother Nature, man is such a piker.)

I think you make the pattern mistake, Cecil. Does the temperature at those times indicate the present temperature or the future temperatures?

Are there any different conditions between now and then?

How about a little thought experiment.

Assume that we build a CO2 generator
Likewise say a methane generator.

Let us flood the earth's atmosphere with as much of the two gases as earth life will stand.

What will be the effect?

Without exception, every time in the past that the
CO2 levels have reached 280 ppmv, an ice age ensued.
The CO2 levels are higher than that today. It would
take a miracle to fend off the next ice age cycle.
I don't believe in miracles.

If man can indeed cause global warming, it will result
in a delay in glaciers covering most of North America
for the Nth time. That is a good thing. The scientists
who feared global cooling in the '70's were right.

However, 1Hz would require a very fast rotating radar antenna!!! Most radar antennas rotate much slower than that, normally in the region of 5 to 7 seconds, although a few ground surveillance radars to rotate a bit quicker. Also 1Hz is a bit slow for the prf of an OHR, they normally sound like a buzzing sound.

It couldn't be something trickle-charging a battery, could it? A local
amateur had trouble with his neighbour's electric shaver. This was left
more-or-less permanently on charge, and produced regular clicks when the
battery was full. And then there are things like cordless phones (often
on-charge when not in use).

if it weren't for politicians who are beholden to extreme environmentalists
who want to destroy the capitalist economic system and throw us back to
feudalism there would be no 'global warming crisis'. Its the damn hippy
culture of the 60's grown up and with money who have bought off enough votes
to keep this topic in the news who are to fault. and by using short term
data that isn't correlated with long term trends they can make the natural
short term fluctuations in temperatures look like catastrophes in
progress... my first statistics course professor said it best... "You can

prove anything with statistics." Just pick your data source, throw out the outliers, apply the analysis that gives you the answer you want, and voila, global warming, huge storms, and Florida sinks into the ocean. Where in the bigger picture the temperature has gone down the last couple years, ocean levels are falling and predicted to fall further, and one good volcano could throw us into another ice age, then we'll all be begging for more greenhouse gasses!

Hmmmm...no flagpoles allowed. Is there any problem with birdhouses? As I
recall, some birds like to have their house on top of a 16-22 foot pole :)

Hang a 22' vertical wire from your tree, small guage, with a few
buried radials and a base fed tuner at ground level, and buried coax
to the house? Would be nearly invisible.

I don't know enough to make any absolute and highly accurate statements on global warming or many of the environmental issues of today.

However, I do know this, lock yourself in your garage with your car idling for a while and you may not leave that garage. And, I do believe some sort of balance existed before man began taxing the natural systems which support life on the planet.

I know the Salmon fishing industry is bust this year. I know there are vast dead zones appearing in the oceans; some Coral reefs are disappearing ...

I have a buddy who is a "camera freak" and he has taken me on freeway overpasses with infrared cameras and shown me the "rivers of warm exhaust" which the cars are passing through--left by the many cars which have preceded them--each preceding vehicle spewing unknown quantities of cubic feet of deadly gases ... I have seen traffic jams with most cars idling--occupants behind rolled up windows--and, most likely, breathing huge quantities of the noxious/odorless fumes. I don't even want to consider power generation plants and businesses' contributions to all this ... the megatons of spent nuclear materials in storage for thousands of years, etc.

I know pollution from China has reached the west coast in increasing-detectable levels and only adds to pollution levels which then travel across America towards the east coast.

I wonder if and for how long we can just go about our tasks and ignore all this? And, is this enough, or should this be enough, to begin worrying prudent men and women?

I do know I can make one truthful statement; "I feel I would like to keep my eyes open and my awareness level high."

I would like to think all this is still incapable of affecting the atmosphere in such force and means as to affect communications! But then, I have come to realize the saying, "truth is stranger than fiction" can contain truth ...

I do think the aluminum/copper/zinc components of my antenna(s) seem to show accelerated oxidation/damage--perhaps this is only imagined ... or, silly fears fed by rumors of acid rain eating away at statues, masonry, limestone, etc?

And yanno, I don't know who I would trust to believe on these subjects. Trust the govt? Naaa. Trust big business who profit from generating these pollutants? Naaa. I just may have lost my ability to trust anyone ... not to mention "statistics manipulations" in general!

Perhaps I am just paranoid in general? Let's all hope ... that would be quite nice, wouldn't it? Sometimes I just love being in error and having only worried about nothing. Perhaps the future will make the truth apparent.

Regards,
JS

No. There are indications are that the cycles which correlate with ice ages, may not produce the conditions for another ice age for the next 60,000 years.

The last global warming peak was 130,000 years ago
and the longest previous cycle on record is 110,000
years. Seems that would indicate that we are already
thousands of years into the next ice age.

Hi all, i am installing a mobile radio into my car soon. I need an antenna that will cover 2 metres, 70cm and uhfcb as the rig only has one antenna socket. I would appreciate any information on how to make one antenna to suite these 3 bands or maybe there is one available. I would prefer to build one. Yes, i know I'm not supposed to be using a ham radio on UHFCB so don't bother mentioning it.

Thanks.

How many of those cycles have been influenced by the release of green house gases by humans?

It becomes almost a non-sequitar to bring that out.

But in search of an answer to your questions:

yes, there appears to be cyclic warming/cooling going on.

This warming/cooling has many possible sources. We're finding outh what they are at this time. Some seem pretty likely, and some are not known as of yet. CO@ levels look pretty convincing, and things like th eMaunder minimum are almost just speculation.

Does the past allow us to predict what is going to happen tomorrow? Not even close. All the cycles we have can only be applied after the fact.

That one is very important, because each and every cycle has individuality. I've just seen something about a meteoric impact possibly affecting the Clovis culture, and possible the glacier flow pattern into the arctic and Atlantic Ocean. That is an individual event, not likely to be repeated.

Neither is the release of large amounts of sequestered carbon. This can happen in more than one fashion. It might come about through large scal volcanic activity. It also might come about through the combustion of those carbon bearing minerals. The source of the release is inconsequential, the effects are not.

Of course, even if it were to blink out tonight, it'll still do the sunrise thing. That's pretty certain.

The issue is those long term cycles. The can predict trends, but can't do a very good job of predicting if it will be rainy today, or if it will even be a cold year or a warm year.

One of my favorite moments is on a cold day, some wag will spout "So much for global warming!" Just a public expression of ignorance, whether GW exists or not.

Let's make no mistake, we are making this experiment whether we want to or not. There is no way that we are ever going to get the new industrial powers to cut down on CO2 emissions. All of this discussion is academic. We aren't going to cut down our emissions.

One of the delicious ironies in all this is that the same people who declare anyone who believes in GW as some sort of leftist have staunch allies who are commies in fact. Go figure.

My guess is that now that we have reached the geometric population growth phase, we will deplete our oil, then our coal reserves. At that point, greenhouse emissions will naturally drop.

As we tap into the "final reserves" of fossil fuel, likely anything that is in the way will fall. Endangered animals, land preserves, pollution controls. It will be pretty quick. Wars will break out over the remaining fossil fuels.

Only so much can be done to conserve. Even if each person uses less energy, there will be plenty of new folks coming along to negate that conservation.

I've seen the future, and it isn't too pretty.

Although there is an alternative:

LOTS more nuc power. Give up on the antiquated and dangerous supply paradigm, in which we just have a few plants running their equipment at about as much power as they can handle, in which any failure makes for big problems. Many smaller and safer plants are in order.

Unless there is some sort of breakthrough, we're going to need to run electric cars. We need a new infrastructure built to handle them.

Wind power is cool, as is solar, but we jest aren't ready to get the huge amount of power needed from those sources.

There are also indications that global temperature correlates inversely with the total number of pirates. The only actual correlation is of course that the respective numbers are plotted on a graph; one versus the other. A cause and effect relationship has not been demonstrated, but the "indications" might lead someone to assume there was one.

UHF Cb in Australia is in the range of 476.425 - 477.400 MHz.
Sorry, i was thinking i was posting in an Australin ng.

So i need an antenna to cover 144-148, 430-440 and 476.425-477.400MHz

Thanks.

Gary,
For what it's worth, take a look at some of the "Comet" mobile 'dual band' antennas. They advertise as being broadbanded and are to some extent (how much, I don't know). I've had no reason to try the 'UHFCB' frequencies, but I do know that at least one of 'Comet's dual-band antennas is fairly broadbanded on 2 meters/150 Mhz. Can't measure on the UHF portions so can't say one way or the other.
- 'Doc

And also keep in mind that "FWIW" thingy! As in, don't take my word for it.

UHFcb in Oz-land is highly likely similar to PMR446 in Europe and FRS in the USA.

PMR446 are 8 RF channels with 12.5 kHz spacing starting at 446.0025 MHz . That means using a Ham radio it must have the capability to be set at 2.5 kHz channel spacing and few if any ham transceivers have that. Also, the deviation is set at a low 1.5 KHz.

So I wonder how UHFcb is operated in Australia ....would a Ham radio with extended range be usable ?

What is a "50% guying radius"? Does that mean 125' from
the tower base to the anchor? Does that mean 250' between
anchors? Are there 3 or 4 anchors?

They certainly are, i'm using a couple at the moment. Our 2 Mtr and 70cm and UHF CB are all 25KHz spacings.
There is talk of changing the UHFcb to 12.5 Kc to get 80 channels instead of 40 but i don't see how this will work as there will still be thousands of 40 channel radios out there with standard deviation splattering all over the newer narrower radios.

As for the pmr446 band, you need a radio that will do 12.5kHz not 2.5 which are available here and i would guess many other countries. From what i read the band starts at 446.0 and goes to 446.1, thus 446.012.5 - ch1, 446.025 - ch2, 446.037.5 - ch3 446.050 - ch4 etc. The deviation for that would be around 8kHz and for 25KHz would be around 12. i think, not 100% but i'm sure it's something like that over here.

Anyhow, i still need an antenna lol.

Guy radius is the percentage length of longest (top) wire to outer anchor.
Three wires at 120 deg spacing. Normally guyed towers are at 80% guy
radius; but due to buying this tower with wires, it was originally at 50%.

I have an efficiency question concerning feed lines. My present system is RG-8X to my 75 meter inverted vee which is about 85 feet away from the shack. I propose to replace some 88 feet of coax with 300 ohm window ladder line that is inserted into the coax run with 4:1 baluns to match the coax on each end. Also at the feed point of the antenna switch from a voltage balun to a current balun (ferrite chock type). By my calculations with a 98 watt generator I will increase the power to the load by about 11-20 watts and with a 985 watt generator, 117-210 more watts will reach the load. Figuring theoretical total system (A) against total System (B) or by just the difference in the 88 feet of ladder line versus coax. What do you think the increase will be?

An acre is roughly 209 feet per side, or 43560 square feet. So, if
I'm guessing that "50% guying radius" correctly, you'll need about 4.5
acres. Call it 5 acres.
The actual 'size' of an acre depends on who'z doing the measuring,
where, and why. It varies.

If I understand you correctly, it is merely the formula for the area of a
circle; pi , r squared.

So 250*250*p i = 196349.54 square feet

DRA wrote:
> Does anyone have the formula to calculate the acreage needed for a
> guyed tower? We have a 500' guyed tower, with guy wire at 50%
> guying radius . Wires would be 250' to outer anchor.

An acre is 43,560 sq ft. Although acres in the US
tend to be typically subdivided sections (640 acres)
and therefore fall into squares that are about
209ft x 209ft, it doesn't have to be square or
even rectangular. Technically an acre could be
1 ft x 43,560 ft.

So it's not simple to say that XX acres will hold
a 500' diameter circle.

Given all that, ONE acre, 500' in one dimension
would be 87.12' the other dimension. You'd need
about six acres in that case to give you a rectangle
500' x 522.72', large enough to hold a 250' radius
circle of guy wires.

A square acre, 209' per side, has a diagonal
measurement of 295'. So if you had 4 sq acres,
you'd have a lot 418' x 418' with a diagonal
measurement of ~591'.

If you used 4 guy wires, and the tower was dead
center in that 4 acres, it appears the 250'
radius would fit.

If you used the more traditional 3 guys, it
would not.

Bottom line is "Acreage" in itself doesn't indicate
the linear measurement of any side of a rectangular
(or any other shaped) lot. You'd have to know the
actual measurements of the lot. But generally
you're looking at at least 5-6 acres.

Think of an acre as ~90 yards of a 100 yard
American football field.

And obviously, none of that accounts for
easements or restrictions on how close to
the edge of the lot you may be allowed to
place your guys due to ordinance/zoning or
good engineering practice.

Hoping I got the math right...

Do you have the requirement that if the tower falls it must all land on your (the tower) property? Some zoning boards require that.

Maybe I'm not reading your description correctly.

Are you saying:

Longest wire length
- divided by -
linear distance from base of tower to guy stake?

If so 80% would be impossible, I believe.
The guy wire would always be longer than
the distance from tower to guy at the ground.
Perhaps the formula needs to be inverted?
Ground measurement / wire length could equal
80% or 50%.

If you're buying this tower, would it be possible
to ask or measure to find out what it's original
guy anchor diameter is/was?

==========
Why not replace the complete coax feeder with twin lead feeder (if you
can keep it away from soil and/or metal) , and use a matching box
directly accepting the twin lead feeder (without ferrite type balun),
be it 300 or 450 Ohms or approx 600 Ohms ladder line ?
It will improve efficiency and above all make the antenna multi-band.

I think you left out the losses in the balun. With a kilowatt even a large (by ham standards) balun will get very warm if you leave the key down... my guess is it's not quite as much as you're saving but comparable. It all amounts to 10%, and that's such a tiny fraction of a S-unit.

Now, if your antenna were an incredible mismatch to coax to begin with, then ladder line makes good sense. Say you want to use your same inv-V on 40M, then you'd run ladder line all the way to your tuner and be in fat city.

My Rigexpert AA-200 has just arrived from
http://www.radioworld.co.uk/~radio/catalog/aa200-antenna-analyzer-p-5841.html?osCsid=7da1c42b40621b06dffec46917ed4fe4

So far I have only used the MFJ 259B. But this is a much better analyser. It is in a class of its own. I input the frequencies for all 5 bands and connected it to my Cobwebb antenna and got an instant SWR reading. It continuously monitors the SWR on all five bands at once. This is only one excellent feature of many. I have not had much experience with antenna analysers, but this one I am very impressed with, so far.

> think the increase will be?

One of the numbers that is hard to come up with is the loss through a
balun. The only number I could find for a voltage balun is a matched loss
of 0.075db, this would be times 2 in your setup. So there is loss, and it's
well known that the loss goes up with miss match. I think you are
neglecting the loss through the baluns and the miss match loss. Remember
your antenna will not be 50 ohms over a very wide frequency range.
Going open wire line all the way or changing to RG8 size coax will likely
work just as well and be simpler to do.

For goodness sake, it is pretty obvious, he means that the guying radius is
50% or 80% of the mast height. So say 100' mast, then the guying radius
would be 50' and 80' respectively.

If you mean the area enclosed in the triangle formed by the 3 guy stakes,
rather than a circle of radius 250', then you can work it out using trig:

h = sin (30)*250 b= cos(30)*250

a = h * (b/2)

total area = a *6

so h =125, b =216.5, a = 13531.25, total area = 81187.5 sq ft

I am want to develop a network of AIS receivers with coverage of the US inland waterways(miss, Ohio, Illinois rivers and the gulf). Searching the web mostly results in sites targeted for cell phone carriers. Does anyone know of any sites that would be more appropriate for this type of need? How do locate sites/towers to be used for repeaters for example?

Ideally well located amateur towers would probably be best.

Thanks in Advance.

I would not take TV ladderline if you have a high standing wave ratio,
and this will happen if you use the dipol for multiband purpose.
I`ve tested a dipol with about 20 m length (67 ft) for 80m.
At first I got almost the same s-meter report compared with a W3DZZ trap
dipol. But after a couple of month I noticed that the received signal
was up to 20 db down compared with the trap dipol. I only used 100 watts
but it broke the TV ladder line. Here I`ve learned what has happened:

http://www.w8ji.com/vswr_reactive_power.htm

I`m planning to build a new antenna with self built ladderline for
multiband purposes for one of the traps of my W3DZZ is broken. Iï¿½ve only
bought the spacers for the new ladder line.

> It will improve efficiency and above all make the antenna multi-band.

Let's see how much improvement. Assuming a 50 ohm antenna,
3.8 MHz, and using Owen's xmission line calculator at:

http://www.vk1od.net/tl/tllc.php

85 feet of RG8x has a loss of 0.478 dB.

85 feet of 300 ohm twinlead has a loss of 0.424 dB.

How much will that 0.054 dB improve efficiency? 1%?

The coax has a 1:1 SWR. The 300 ohm twinlead has a
6:1 SWR. That makes the losses almost equal. If we
were talking about RG-213, the losses would be
0.308 dB, 0.116 dB better than the 300 ohm twinlead.

The following is becoming a myth: "One can ignore
the losses in twinlead and ladder-line."

Also - maybe he doesn't want to use a "matching box".

I have a 135-foot dipole fed with approx 100 feet of home-made ladder
line and am incredibly happy with its performance from 80M all the way
to 15M.

Much of the joy of the ladderline was not in buying the parts to make
it, but making it from stuff on hand. I had a sheet of 1/8"
polycarbonate that I cut into 4"x3/8" strips, then drilled and
notched, to put a spacer every foot using tie-wires. Others boil
wooden dowels in paraffin for the spacers (the method recommended by
the 1930's ARRL Handbook). Seeing the ladderline go up 85 feet to the
middle of the dipole is a pure joy!

11 - 20 watts represents only 0.5 - 1 dB, which would virtually never be discernible by the other station. As others have noted, even this insignificant potential gain would be reduced by balun loss. But what no one else has mentioned is that the ladder line loss can increase significantly, possibly even dramatically, when it gets wet. Any improvement you'll see from the proposed change will be due entirely to placebo effect.

Why those are good choices for lengths can be seen on
the following diagram:

http://www.w5dxp.com/pnts130.gif

You are relatively close to a low-impedance/current-
maximum point on all HF bands.

If you switch from coax to ladder line and baluns or tuners, you are
going to lose a bit of efficiency I bet.
I always have when I've compared the two on that band.
You are converted from a pure and simple system which is a 50 ohm
radio, feeding 50 ohm line, which BTW at 75m is very low loss,
into an appx 50 ohm load. This "pure" system is probably 95%+
efficient on the 75m band as long as the coax is not junk.
In my opinion there is no better method of feeding a single band
dipole. Anything else is pretty much a step down as far as I'm
concerned. The *only* reason I would ever run that way is if I
wanted multi band use using ladder line and a tuner.
But in my case, I prefer multiple dipoles fed with a single coax.
The decrease in loss switching from coax to ladder line *on 75m*
is so small as to be nothing. But then you have baluns and tuners.
This is what is going to spoil the food. You will actually end up
with
a net loss at the end of the day. Maybe be a small loss, but I
bet it will be measurable on a meter if you used an A/B switch.
It was in my cases. Then you have the moisture issues, etc..
Do what you want, I prefer coax when feeding dipoles.
I usually use 213 on HF here at the house.
But at 3 mhz, even RG-58 is fairly low loss.
The mini 8 you are using should be a bit better than rg-58.
I think it's slightly larger and using foam if I remember right.

I assume Dieter that this is your recommendation of the article.

That article uses the term 'reactive power' in a non-conventional way,
though the term is a well known one (ie has a conventional meaning).

Conventional use is that the term 'apparent power' is applied to the
product of RMS voltage and current flowing into a two terminal load, and
the units are VoltAmps (VA), not Watts as used in the article.

Reactive power is the reactive component of apparent power, and expressed
in units of 'VoltAmpsReactive' (VAR).

'Real power' is the real component of apparent power and expressed in
units of Watts (W).

The relationship is that
apparentpower = (realpower^2 + reactive power^2)^0.5 .

This is all basic lumped component AC circuit theory, and holds at RF.

However, basic lumped component AC circuit theory is not a good way to
analyse antenna systems, expecially to determine transmission line losses
cause by highly reactive loads (which is what that article tries to do).

Sonny,

I have resisted the temptation to tell you that the question is wrong rather than to answer the question... however...

You are trying to compare two configurations that are not optimal.

An optimal coax configuration would have a balun, usually at the antena feed point so your coax loss budget is short changed a balun.

I assume from the fact that you have proposed coax that this is a one band antenna. You haven't made it clear whether you can use an ATU to transform the load to suit the tx, I will assume you can.

Why do you need two 4:1 baluns / transformers? The dipole is already an approximately balanced load and loss on open wire line with a VSWR of 4:1 is still quite low. You could just attach the feedline directly to the antenna, and use a 1:1 balun at the ATU. Alternatively, you could lengthen the feedline a little so that it was an electrical half wave and dispense with the ATU (still need the balun).

In the case of the latter (an electrical half wave of open wire line, 1:1 balun at the tx) you will achieve the lowest loss, but it is just a few tenths of a db better than the balun/RG8X config if you work them through.

The open wire line might not be as easy to route into and around the shack, and depending on construction, more affected by water.

Owen

will be to remove the RG-8X and it's high attenuation and install all
JT-2015 (RG-8 Type) from R&L Electronics. Also to put a good 1:1
balun at the feed point.
I have a 160M windom and a G5RV and will dedicate this
inverted vee antenna to 75M. This will be not used on 40M due to the
high resistance on the second harmonic with the current balun.
Yes the added baluns for the ladder line would increase the
insertion loss and yes the wet ladder line is a poor conductor. And
the cost will be spent for a more efficiency designed system.

There is so little loss at 3.5 mHz for RG8X you would have a hard time
telling any difference.

In one short word: imperceptible.

Using twinlead or ladder line is a good idea if you're feeding an antenna
that has a high SWR at the feedpoint on some of the frequencies you're
going to use it with, but at 75 meters, RG8X vs. ladder line will only
make a small difference if the SWR is at all close to 1. Less than half
a decibel, or a tenth of an S-unit!

Sure, it might make enough difference on very weak paths, but most of the
time nobody would be able to tell the difference on a direct on-air A-B
test!

And even that advantage almost disappears when the ladder line is wet.

Like I said, the picture is quite different at high SWR.

Sonny, run the numbers at http://www.vk1od.net/tl/tllc.php before you spend the money.

BTW, it will make NO difference on receive since S/N ratio on 80m is almost entirely determined by band noise and small change in TL loss will make no significant difference. Change in TL loss will affect the strength of your transmitted signals.

YOu have had many answers to your question, but have drawn the wrong conclusion. If you replace the rg8x with some of the best low loss coax (lmr400 for my example) you go from about .7 db to .2 db of loss on 80 meters. That is .5 db less loss. You will almost need an electron microscope to see the s-meter move . Also 80 meters has so much noise on it most of the time, you will not be able to hear the difference. I think it was one db that was suppose to be the minimal detected difference in hearing when the db scale was first put into use.

It may seem that if you have a 100 watt output transmitter you will go from about 85 to 95 watts in a matched system. This may seem to be a lot , but on the receving end it will not be noticed.

On maybe 20 meters and higher, especially 2 meters and up it does make good use of the money to go to a higher grade of coax for weak signals.

Spend your money on something more productive.

True, but we still aren't there.

It's very misleading to quote "VAR powers" in the kilowatt range,
because the only power available to melt the feedline is 100W from the
transmitter. There is no magnification of real power.

The high value of "VAR power" is a theoretical result of the large RF
currents in the system. These result from an antenna feedpoint impedance
that has a very low resistive part and is almost entirely reactive. The
large RF currents are a genuine physical phenomenon, as also are the
high voltages a quarter-wavelength back along the feedline (if the
feedline is long enough, of course)... but if there were no losses in
the feedline, these would have no further effect. In spite of the wild
values of impedance, current, voltage, VSWR etc, if there were no losses
in the feedline then all of the RF power would still reach the antenna.

In a real feedline, the effect of the high currents is to divert almost all of the available RF power away from the antenna and into the feedline's own resistive losses - skin-effect losses in the copper conductor, and dielectric losses in the plastic. Both of these result in heating and softening of the plastic, which makes the dielectric loss even higher. This tends to divert even more of the available power into the weak spots, where the plastic finally melts.

But there is still only 100W available to do the damage.

No argument about the final conclusion - it ain't gonna work - but I don't care for the explanation. There's no problem with "VAR power" for anyone who already has a firm grip on the concepts, but it is not a good way to explain those concepts to a newcomer.

There is indeed no net increase in real average power.
However, "magnification" seems to be a poor choice of
words since its definition contains such words as
"apparent", "seems", "exaggerate", "overstate", ...

"magnify - to cause to *seem* greater" certainly describes
a feedline with 100W source power and 200W forward power.

> But there is still only 100W available to do the damage.

True, but a 100W laser can do a lot of damage. :-)
And a *magnifying* glass can start a fire.

I think you are right, the referenced link of W8JI mixed up the definitions. He used "kilowatts" instead of "1000 VAs". But for me the text was very helpful. It also will give newcomers some information about problems with short antennas. If you ask: What is responsible for the losses of an antenna construction ? The answer would be: The losses are proportional to the " Apparent Power VA" It`s "Scheinleistung" in German language. I didn`t even know the term before it was mentioned here.:(
I found this schematic in the wikipedia with the different terms Real Power, Reactive Power, and Apparent Power:

http://en.wikipedia.org/wiki/Image:Power_Triangle_01.png

So if we use a short antenna, e.g. 20m for the 80m band or even the G5RV we should use parts that can handle the "Apparent Power". I`ve seen Sonny has already made up his mind using koax for the 80m Band. This probably is a good idea, and I`m planning to build a monoband for my favorite band and multiband antenna fed with a low loss ladder line to cover all the bands. I`m not quite sure if a folded dipol as a monoband antenna fed with ladder line would give better results as a coax fed dipol. I have the equipment to match both kinds of feeding lines.

There's your answer. And here's the readers digest version of it.

As a rule of thumb, if you are going to use an antenna cut for a specific band, cut it for that, and use coax, and a balun.

If you want to have multiple bands from one antenna without traps or tricks, use ladder line and a tuner.

The ladder line can handle the wildly varying VSWR, and the tuner will, well, allow the Xciever to see an impedence it likes.

That depends on the laws of your country. In the US it would have to
be type accepted by the FCC and ham radio would not qualify.

Source record: 25283

Hi,

I have been running many automated NEC2 runs to optimize a 5 band quad. My criteria included bandwidth and all my runs to date have been done assuming direct feed with 50 Ohm coax.

I'd like change the criteria and allow the feedpoint impedance to drop below 50 Ohms now, with the expectation that I would use a gamma match at the feedpoint. Using a gamma match at the feedpoint, for me, would be more advantageous because this means the driven elements of the inactive bands will truly be closed loops (eliminating the need to do other things to achieve this, relays, specific lengths of coax, etc.). I would place a choke at the gamma match feedpoint as well.

Since (2.5:1 SWR) bandwidth is still something that is important to me, I need a way to calculate it. Would it be a mistake to take the real impedance at the center design frequency, make this the line Zo and then take the reactance at the center frequency as well and offset the reactance at all frequencies this amount?

For instance, if the frequency was 25 - j10, If I make the line Zo = 25 Ohms and then add +10 to all the reactance values, can I use the resulting SWR value to judge bandwidth. I know this assumes that the gamma match is a perfectly linear circuit, which I am sure its not. Is there a better way to estimate the bandwidth and how off could I end up off? Is there any better way to do this?

Hi Scott

Have you thought of recording the antenna's input impedance at several
frequencies in the band of interest, then plotting them on a Smith Chart?
The plot will be a smooth circular trace going clockwise with increase
frequency so it will be easy to know how many frequencies are needed to
plot. maybe 5 is sufficient.
When the antenna's impedance is displayed on the chart, it becomes easy to
estimate the effect of something like that + j10. Reactance added in
series will move the impedance along the lines of constant R. When added
in shunt, the impedance moves along the lines of constant 1/R (admittance).

The short answer is no. There currently is no river system wide
network of receivers managed by any company or agency.

We currently have coverage in three areas, but in order to provide a
useful service for safety, monitoring and performance management, more
coverage will be needed. This could either be under the umbrella of
either a non-profit organization or as a standard business.

Now that we've covered the premise of the question.... any help?

I didn't see an "attack". I saw a sensible question
about a cloudy issue.

I don't know how you would feel about loaning
tower space to a navigational aid, but I wouldn't
do it. I'd do it for some hams doing APRS or
something like that. But not for a system that's
designed for safe navigation by commercial vessels.

The last thing I would want would be for something
to go wrong with the install, the tower, the feedline
etc and a barge crashes and loses a billion dollars
in cargo and kills a dozen people.

Now exactly what was that good reason for putting
those gizmos on somebody's ham tower?

Oh. What I saw was a question answered by another question followed by 4 exclamation points. When the number of exclamation points exceeds 3 when 1 would suffice, then it is an attack. This is according to the AI4QJ internet handbook.

So you have answered the antithesis of his question. Actually the question was "where are appropriate sites?" and your answer apparently is that your site would not be appropriate (if you had one). The question did not request information on sites that were not appropriate, however.

>

A question presumably asked at a future court hearing in the event of a lawsuit. Of course one can sued be sued for almost anything and I would have to agree that if one never does anything, the chances of being sued are minimal.

I really do need to clarify here, the gizmo in question is an AIS receiver. An AIS receiver denied at its birth the ability to transmit or ever grow up into a transceiver. It is listen only.

As it stands you are in sum danger of interfering with the AIS system in that it operates on 161.975 and 162.025 so I imagine it could be some how possible for your VHF set to break in such a way that it broadcasts over the traffic on these channels. Not probable I would think.

As for causing collateral damage, AIS is an aid to navigation, not a replacement for navigation. Given that AIS is a digital communication even with a transceiver it would take effort to construct a message that might cause someone to make a decision leading to an accident.

On the other hand, by supporting an AIS receiver for us to use to archive data, you can help with the accident investigation after the fact. Or help prevent an accident by allowing real-time proactive monitoring of shipping behavior, for example by that captains company. This is already used in the trucking industry.

Thanks to everyone who responded. If you have a VHF line of sight to any of the inland waterways and would like to help please email me. Here are some AIS related links that you might find of interest.

Then for the benefit of me, at least, who doesn't
know a thing about the gizmo, what exactly does
it do to aid navigation? I was under the impression
it received position and course info from commercial
vessels. You mount it on your pleasure craft and
it helps you to know if you're in the vicinity
of potential traffic.

What exactly is the significance of having a
network of these receivers on land? ie who is it that
is receiving the data and what is the data?

Es is not all that well understood, but current thinking is that it is not tied in to the solar cycle in the way you intimate. Es peaks in summer and winter, the summer peak being better. You are experiencing the early days of your summer peak, just as downunder we are seeing the early days of the winter peak.

Look at some Ionograms for signs of Es, and treat what you hear about it with suspicion (yes, including this). I heard a theory propounded by a net controller to his flock on 40m a couple of days ago that HF sporadic E goes down when VHF sporadic E goes up. How is that?

the longer answer, found in a few short searches is, that its coming... see the presentation at http://www.gicaonline.com/media/tools/070827_cris.ppt#1

You state that this could be a 'non profit' or 'standard' business... and that it could be for safety purposes... in which cases i agree with others that have stated that there is a possible liability issue, whether you see it or not. once something like this is advertised as a method to improve safety there is a penalty to pay if it becomes unavailable. Also, renting space on a tower to a commercial operation can expose hams to loss of protection of their towers as amateur in some areas... in some places it is considered the same as changing the purpose of a building from residential to commercial/industrial which could endager protection under prb-1, or at least cause headaches for an unsuspecting amateur.

You also now state 'we have coverage'... is that you personally, or you as this hypothetical 'non profit' or 'standard' business?? if so, please state your entity rather than hiding behind a gmail account. and let us see what type of product you have produced in these 3 areas.

<NeedAntennaSpace@gmail.com> wrote in message news:e9a3488e-920f-44cf-855a-92d236ea5b61@x35g2000hsb.googlegroups.com...
The short answer is no. There currently is no river system wide network of receivers managed by any company or agency.

We currently have coverage in three areas, but in order to provide a useful service for safety, monitoring and performance management, more coverage will be needed. This could either be under the umbrella of either a non-profit organization or as a standard business.

Now that we've covered the premise of the question.... any help?

Thank you for seeing it. Imagine some kind of incident
occurrs where this system failed. They examine all
the equipment on the ship, on land, wherever.
They find that the tower was used, 50 years old, purchased
from an SK ham estate sale, installed by some local
amateurs over Labor Day weekend, using the original
guy lines and hardware that were on the tower in
it's previous install, and in violation of someone's
CCR's because it now holds some kind of commercial
aid to navigation and the tower owner was away for
the weekend visiting the Hamfest in Dayton.

Even if nothing goes wrong, there's something very
wrong with that picture.

Not to mention, I still don't understand what all
these ground based RECEIVERS are supposed to do.
How does a receiver on shore assist navigation
for a vessel in the water?

AIS is not only an aid to navigation, it's just like APRS for ships, it allows those ashore at remote locations to monitor the position of vessels. On a river system I guess it could be used to monitor traffic flow, optimise lock usage, find out when your vessel is likely to arrive for unloading etc.

Dear "DRA" (no call sign or identification):

It is highly likely that you will be required to own all of the area where the tower could fall. Assuming 10% extra length and a square "lot," that would be 1,210,000 square feet (about 28 acres). Not only will you be required to have enough area, but you will need to have a licensed engineer certify the design (not a simple task with a used tower) and you will need to negotiate with the FAA/FCC as the height is above 60 meters. (This assumes that you are in NA.)

500 feet is about optimum for a 3.5 MHz beam, but too high for the remaining HF bands. With insulated guys and lots of radials, a 500 foot tower could make a good vertical at 1.8 MHz.

Regards, Mac N8TT

Date: 2008-05-30 15:36:25 UTC
From: scooterspal <tfg1@mindspring.com>
Message-ID: <maV%j.2394$uE5.1377@flpi144.ffdc.sbc.com>
Source record: 25209

Hello and thanks for ahy help you can provide.

I have a small assisted hearing type transmitter that normally uses the shield of the mic cable for the antenna. I need to change to a fixed antenna for a particular application where there is no mic cable to extend out.

The manufacturer says the antenna wire for this 651.85Mhz unit should be 48" long.

Can anyone tell me what that would equal in a rubber ducky antenna?

Thanks.

==========
The transmitter operates on a wavelength of 300/651.85 equals 0.460 m or
460 mm.

48 inches equals 48*25.4 equals 1219mm So the 'recommended' antenna is
1219/460 equals 2.65 wavelength.

Does not make sense to me

So you want the area of a circle 250 ft in radius? pi * r^2 =
3.14*250^250 = about 200,000 sqft. An acre is roughly 43000 square
feet, so about 4 and half acres.

You appear to be posting from the US, so I thought I'd mention that if this transmitter is an unlicensed "Part 15 Intentional Radiator" (I don't know what an "assisted hearing" transmitter is, so I might be wildly off base), you'll be running afoul of 47CFR15.204(c) if you use any antenna other than the one supplied with it.

Just trying to help :-)

It sounds to me like it was an observation, not a theory. He didn't get to the point yet of developing theory or fact from the observation. Since there would be no motive for his telling a lie it is probably a real observation. The question as to why the onservation is true could be due to several reasons, possibly related to conditions where the VHF and HF transmissions occured at different times or different places or that the VHF propagation was due to other phenomena such as tropospheric effects. Personally I encourage HAM radio propagation observations although I rarely believe the first theory I hear that attempts to explain such observations.

This is a legal device. You can find them at Comtek (www.comtek.com).

I'm just trying to replace the antenna system they are using, which is
a lapel mic with about 48" of shielded cable between the 1/2" connector
and the mic head, with a fixed, shorter high-gain (rubber ducky type)
antenna.

Can anyone help me to accomplish this? What do I need in terms of
the antenna... the exact type?

Thanks.

'high-gain rubber ducky' isn't that an oxymoron?? rubber ducks are usually
much lossier than full size antennas.

I'm confused, now.

Their web site (www.comtek.com) shows the newer models operate in the 216-217Mhz band. I have a frequency counter. Is there a way I can make a wire loop and set the trasmitter near it to pick off the operating frequency?

Thanks.

OK. I have tested the frequency and found it to be 75.489Mhz. Should have done this first, sorry for the confusion. Comtek did make systems that operated betweeh 72 and 76Mhz. This is one of those.

That said, where do I stand antenna wise?

Thanks!

yes, make a wire loop, put the transmitter near it and read the frequency...
just like you said.

Depending on how large a distance you want it to cover, you may get by with a considerably shorter antenna than the 48 inch recommended size. But you also didn't say, that I could see, that there was a problem using a 48" piece of wire. Obviously it's not too critical since in use the mic cable can be bent in all sorts of different shapes and it still operates. In other words, try to not make this more difficult than it needs to be. If you need the mechanical antenna to be shorter than 48 inches, just wind that length of wire in a spiral, spaced out as much as you can accommodate. Try that and see how it works. Easy enough? If you need higher performance, that's possible, but in general very short antennas won't be as efficient as straight antennas long enough to be self-resonant at the operating frequency. If you need good performance from a short antenna, get a system that operates at a higher frequency.

Cheers,
Tom

In all likelihood, no one on the other end will ever be able to tell the
difference after you make the changes. Neither will you.

Years ago I noticed a change in the color of the light being emitted by the Sun. I also noticed a difference in how it felt on my arm while driving the car. At the time I attributed the differences to my own personal aging. Lately I have begun to think that my first suspicions were correct. Something had changed in the nature of the solar output.

This would also partially account for the melting of the polar ice caps on Mars. I find it odd that I haven't been able to find any confirming data from respectable scientific sources illustrating a change in solar output. Maybe I missed it?

Source record: 25224

Hi, all concerned:

Does anyone have an EZNEC model file for the TH11DX, please?

I'd like to see if it's worth the effort, to extend the log driven cell "out front" to 1 or 2 elements for 6M and "out back" to one element for 30M.

Issues are the HyGain 4K balun at 6M, and the use of parasitics to manage feedpoint Z.

you can't trust mars, we have landed too many probes there now and they are
obviously contributing to the warming. They are even measuring warming on
Jupiter and we have only had one or two probes burn up there i think.

Which model do you have?
http://www.comtek.com/sitemap.html
choose the model, and the device frequency range will be listed. They
only show three frequency ranges, 216-217 Mhz, 72-76 MHz, and 76-78
MHz. They also have several options for external antennas, but I
think these are primarily for the base transmitters.

As mentioned in an earlier reply, if you build your own antenna, the
device _may_ become compliant.

Is that all a rubber ducky antenna is? 48" of wire wound around a
flexible core of some type?

If so, what do I look for (type, model, etc.) if I want to purchase
one to try out?

No, that isn't all that a 'rubber duck' antenna is, wish it were
that simple. Since the question was asked, I have to assume that you
aren't exactly familiar with what a transmitter 'looks' for in an
antenna, or how that 'looked for' thing is arrived at. (And if you
aren't sort of 'involved' in radio stuff, why should you be?) Once
you learn about all that stuff it really isn't all that hard to
figure. But that 'learning' can certainly be a real chore! :)

> - 'Doc

Not sure what posts you're referring to, Doc. But
yours look fine to me. No odd arrow charcters.

Regarding this antenna for the low power transmitter,
I expect there will be a bit of grief coupling a
rubber duck, or anything else, in place of what
was the mic cable.

Are they somehow using the shield of the cable
as the antenna? If so it's likely floating and
not directly connected to circuit ground. Plugging
a duck in place of the mic, with typical connectors
and adaptors, would likely not connect the antenna
element to the "antenna terminal" of the device.

I have no doubt that modifying the antenna would
alter the intended tuned antenna circuitry as
well as violate the type acceptance.

Perhaps a bit more about "what is the intended use"
from the OP would help.

Thanks, Lumpy. Now we're getting somewhere.

Yes, they are using the mic cable shield for the antenna. Cable is 48" long with a 1/8" phone plug on the end. The shield side of the mic connector is floating, that is correct.

I would be connecting the antenna to a new socket of some sort. A BNC if I can make that fit this rather smallish casing.

Can you give me any starting point for the antenna itself? If I was to connect it to the existing lead off the coil, the one that now goes to the mic shield... remove if from there and connect it to the center pin on the antenna. Would the outer ring of the BNC go to battery negative ground?

The manufacturer mentioned using a 5K resistor on each side as I recall. Does thie affect the gain in any way?

I'd only be guessing. Perhaps the 5K resistor(s) are
part of the 'float'.

What kind of signal are you going to transmit
if you aren't using the mic? Just answer generically
if you're an Al Qadea operative or something. ie where
on the gizmo will you connect the audio(?) that you
want to transmit?

If you're injecting the signal somewere else besides
that mic jack, try just temporarily clipping a 48"
piece of wire to the OUTSIDE of the mic jack or whatever
terminal connects to the shield of the mic cable (your coil?).
If that seems to work, then consider your rubber duck or other
options.

The mic jack may be designed to shut power off when
disconnected. You might need to plug a dummy phone
plug into the jack to get it to power on.

Just connecting random wires or antennas to the thing
won't damage anything as long as you only connect to
one point (don't short two terminals together). I don't
think I'd be connecting any antennas to power ground
unless I was really sure of how the thing works.

The outer ring of a rubber duck does essentially
nothing on most rubber ducks.

As others have mentioned, you're probably going to
get LESS of a signal by going to the shortened
duck antenna over the original 48" wire.

Is there a schematic somewhere?

Maybe not from any practical standpoint, but I could see the
difference on a meter when I fed both a coax dipole, and a
ladder line dipole using the same tuner, which has antenna
switch, and meter built in.
So I could A/B real fast. I could see a slight difference on
receive switching between the two. And if it's enough to see
on a meter, I consider it a noticeable amount.
Most of the signals were in the 20-40 over 9 range being 75m,
and I'd see about 5 db worth of difference between the two
antenna/feed lines.
Course, I make no claim as to the exact DB amount of difference,
but I could see it on a meter.
After many years of 75 and 40 m operating using mostly NVIS
paths, I've come to the conclusion nothing will beat a dipole/loop/
turnstile fed with good coax for sheer system efficiency unless
say you had a run of several hundred feet or something...
Which of those three doesn't really matter much, although I
prefer the turnstile over the other two if I had a choice.
Nothing wrong with a loop, but in my cases, some sections
end up sagging closer to the ground, and you are often a
bit more prone to ground losses, and also overall performance
if sections of heavy current are low to the ground.
With a dipole or turnstile, max current is at the feed point, so
the ends of the wires height above the ground is often not quite
as critical.
As far as I can think of, only Cecil's no tuner/no choke system
would let a ladder line fed dipole equal or slightly beat a coax
fed. And in that case, I'm not sure how noticeable it would be,
being as the 213 I use is quite low loss at 3-4 mhz.
But like you say, for on the air, many would probably not
notice much. #1, you would have to do quick A/B transmit
tests for them to notice any difference, and also make sure
fading doesn't skew the results. It would be best to test with a
stable ground or space wave signal.
But... I still prefer coax.. I want every drop out I can get, and

I also much prefer the convenience of coax. IE: with most
antennas, no tuner required. And really not even a "balun"
required if you roll a choke out of the feed line itself and tie
wrap it. Weather is no issue with coax. I can have it sitting
in standing water with no problems.
The only time I use ladder line is mostly experimental
antennas where the feed point impedance is not the usual
50 ohms. If the mismatch to coax is high, ladder and the
tuner makes sense.

Most of it had to be the antennas. Going from almost no loss open wire to
much higher loss rg58 would be only 1 db at the most on 75 meters.
You still need a magnifing glass to see the smeter move this much on a ham
receiver.

5118. Does anyone have an EZNEC model file for the TH11DX

Hi, all concerned:
Does anyone have an EZNEC model file for the TH11DX, please?
I'd like to see if it's worth the effort, to extend the log driven cell "out front" to 1 or 2 elements for 6M and "out back" to one element for 30M.
That would solve several nagging band-coverage problems.
Possible issues are the HyGain 4K balun at 6M, and the original designer's use of parasitics to manage feedpoint Z.

The original use for the device was to transmit from
someone speaking to someone who was hard of hearing.
Assistive listening is what it's called, I believe.

The same company offers essentially the very same product
WITH the antenna for sending a progam feed from an audio
mixer to the producer or director during a film or video shoot.

That's my need. I'm simply patching the output of my portable
mixer into the existing mic jack on the unit. I'm doing away
with the 48" extended mic cable and the antenna that is part of it.

Holding out 4' of wire will not work for my needs. I need to use
a fixed antenna.

Will any antenna designed for 75-76mhz work?

What about the tuner loss? And.. I was using the least amount
of inductance needed to tune.. The difference was noticeable on a
meter.
So that would tend to indicate the difference was more than 1 db.
The 213 I use at the house would be even lower loss than the 58,
but I do use rg-58 sometimes when portable, etc..
Doesn't do any good to use a slightly lower loss feed line, if the
tuner
needed to match causes more loss than the feed line saves vs coax.
And tuners will vary also. Also setting the tuner itself can lose even
more power if the minimum inductance is not use. It's not too hard
to lose up to 20% of your power if the inductance settings are wrong.
I'll still stick with coax and no tuner. :)

Aside from the differences in level/impedance between
your mixer and the original mic, the simplest hurdle
is the floating shield on the orig mic that they
use as the antenna.

I don't recall now the freq of your device. But antenna
length probably won't make a huge difference. A 48 inch wire
might give you just the same performance as a 12 inch wire.

If you're going into the guts of the transmitter to
connect the mixer, that will reduce the antenna float
problem. But if you're somehow plugging the mixer output
into the mic input, then the shield/ground of the mixer,
perhaps all the way back to the 3rd lug ground in the AC
wall supply (if it's AC powered), will become the antenna.

There might also be some kind of DC power on the mic
line from the transmitter to power a condensor mic.

There's just a ton of variables. And it all seems to
hinge around them using the mic cable for the antenna.

PERHAPS a simple solution would be to use an impedance
matching xformer (Shure, RatShack etc) between the mixer
output and the transmitter input. Make your mixer to
transmitter cable 48 inches long, use the xformer between
the mixer and that cable, and use the cable as the antenna,
as originally designed. In other words, replace the mic with
a transformer and appropriate connector to mate with your mixer.
The transformer would tend to isolate the mixer from the antenna
somewhat, as well as matching the two audio levels a little better.

[Transmitter]---mic cable 48"---{|xformer|]--[Mixer]

Lumpy

Did you do a lot of those Emergency Broadcast Warnings?
Yes. Had it been an actual emergency I would have hid.

Um, no, it does not. The actual amount of land included in a particular property will vary only as far as the truthfulness of the describer is concerned. 1 acre will always be 1 acre. Or about 43560 sq. feet ...or for those of us with more modern measuring systems, 4050 square meters or about .4 hectares.

Robert Smits:
> Um, no, it does not...

I'm sitting on a half acre that is
short by 500 sq feet due to an easement.
It's legally recorded as an acre.

An acre doesn't have to be square or rectangular.
It could be 1ft wide, it could be 209 ft wide.

An acre could include a penninsula or boot heel
or other odd shaped piece of land.

An acre could exist entirely on that odd shaped
piece of land and be triangular in shape or
any other polygon shaped.

An acre could be measured from the theoretical
centerline of a stream in which case it would
mean you don't have land on that stream portion.

An acre could be on the side of the hill
and therefore the ground distance from one
side of the acre is FARTHER than the 2 dimensionally
measured distance.

An acre could have been converted from a
metes and bounds survey system and be quite
inaccurate but still legally recorded
as an acre.

An acre could have been measured decades ago
and could have been inaccurate due to the
technology or politics of the day.

An acre could have been accurately measured
at one time and then the land shifted and
changed dimensions.

An acre with rectangular borders sits on
a planet that is the shape of a distorted globe.
2 dimensional straight lines and square corners
will become distorted when applied to the earth's

surface.

Bottom line, for purposes of putting a tower on
a piece of real estate, is that "how many acres"
will not be a very conclusive number. More accurate
would be -"I need a lot that is at least XX ft by YY ft".

Of course it is. It is still an acre lot. The fact that you can't use 500 square feet because there's an easement on it doesn't make it any smaller, even though your usable portion is.

> An acre doesn't have to be square or rectangular.
> It could be 1ft wide, it could be 209 ft wide.

Absolutely

> An acre could include a penninsula or boot heel
> or other odd shaped piece of land.

Yep

> An acre could exist entirely on that odd shaped
> piece of land and be triangular in shape or
> any other polygon shaped.

Yep. The lot I live on is about .91 acres, but it's a corner lot and is almost triangular in shape.

> An acre could be measured from the theoretical
> centerline of a stream in which case it would
> mean you don't have land on that stream portion.

Yep

> as an acre.

Despite whatever legal fiction the land registry uses to describe it, it's either an acre or it isn't. An acre is a standard measure of area and it never changes.

> An acre could have been measured decades ago
> and could have been inaccurate due to the
> technology or politics of the day.

Whether or not land you bought was accurately measured at the time or not has a bearing on how much land you have, but it has no bearing on the amount of land you have in an acre. If you buy land that is described as a one acre lot and it's actually a 0.8 acre lot, then even if some charlatan described it to you as a one acre lot, it's not - it's a 0.8 acre lot.

> An acre could have been accurately measured
> at one time and then the land shifted and
> changed dimensions.

Yep. And it's time to measure it again.

> An acre with rectangular borders sits on
> a planet that is the shape of a distorted globe.
> 2 dimensional straight lines and square corners
> will become distorted when applied to the earth's
> surface.

As you've already pointed out, lots come in all shapes and sizes, although the distortion you get from the earth's curvature is so small for the purposes of this discussion it's negligible.

> Bottom line, for purposes of putting a tower on
> a piece of real estate, is that "how many acres"
> will not be a very conclusive number. More accurate
> would be -"I need a lot that is at least XX ft by YY ft".

I agree completely with the last statement, and would argue further that anyone putting up a five hundred foot tower should have at least a five hundred foot radius from the tower centre - meaning a lot that is at least 1000 feet by 1000 feet, assuming a square lot with the tower in the centre. That's a helluva lot of hardware if it drops.

I think we're largely in agreement here - what is sometimes described in terms of acres is often inaccurate, sometimes wildly so. My point was that the size of an acre DOES NOT change, whether or not the lot is measured accurately. Obviously the size of a LOT can change, especially if it's waterfront property.

I will try to describe it best I can.

Its something loose but cant tell from Visual

10 meters when I rotate the antenna will go Numb as the antenna moves and wiggles. It will settle down when it stops sometimes. but If i tx and drop it will come back to hearing. Anytime the wind blows does the same thing.

NOW here is the weird part, If I rotate while KEY DOWN ... SWR stays flat .... but I unkey and it goes numb while moving.

Weirdest thing Ive seen. Driving me nuts too.

Im thinking trap but if it was loose it would stay that way i would think

Help, going crazy.

Scotty,
No idea where, but it does sound like an intermittent connection problem. Since the feed line 'loop' around the rotor does the most moving, I think I'd check that first... then everything else, naturally. Then again, since the problem area is always the last place you check, start at the most unlikely place and work away from it...

Thanks Doc, But if it was Feed Line Id assume 20 and 15 would be
effected, but they are not :)

Ill get up there soon and take a peek

OR a bad connection on a Element (close to a trap)
(High Voltage Point RF wise, xmitting arcs it to make intermitant
contact at that joint- Maybe need to use No-Ox at EACH joint
on antenna?? Jim NN7K

I would take each piece apart a little, put some no-alox or penetrox on all
the joints and reassemble - one joint at a time until I had done them all.
It would probably be a good idea to use some emery cloth on the joints
first.
Probably oxidized alum joints. Alum oxide is an insulator, so the electrical
joint compound will probably fix it.

It's much more difficult to make a reliable "dry circuit" contact (low voltage and current) than one handling substantial power. The reason is that any oxidation or other crud will ruin a dry circuit contact, but higher voltage and current will burn through the crud to make good contact. So it's no surprise that your situation improves when you hold the key down. I had some open frame relays in a plastic box outside doing some antenna switching which would crud up after a while. But all it took was a "dit" from the transmitter, and they'd behave for a while. You apparently have a situation where the contacts are re-oxidizing rapidly (as aluminum, for example, will do), or where some contaminant runs down over the contacts to recontaminate them after the transmitter key-down period. Track down the signal path, and put something like DeOxIt on any contacts. The oil will prevent re-oxidation, and normal wiping action should push the oil out of the way in the contact area to allow good contact. I wouldn't use a grease like NoAlOx unless you have a pretty fair amount of contact pressure. I've found that WD-40 works quite well, too. You might find it handy to at least find the problem area.

Well I finally got the rope cut, I Duct Taped my Tree trimmer extended to 2 10 foot Rat Shack Mast pieces I had, that and getting on the ladder a bit I was able to get up into the rope enough to cut it.

Now the Good News is

I changed Reels in the wrist rocket, I was using Open Faced but noticed all the ones on the net had a Zebco. So I grabbed a spare zebco, walked out and zinngg right to the top of the tree, and then it slid down slick as can be. Sent up the messenger string (small nylon) and pulled the main cable back over and up went the antenna. All is well now, I got frustrated cause the open faced would let it spool out proper it was either short or hung up. Zebco worked peach.

Thanks for all the help folks

Scotty W7PSK.

==========
Agree with the above because the matching device (tuner) is NOT 100%
efficient , hence some (hopefully very little) RF power from the
transmitter will be converted in heat inside the matching device.

Source record: 25120

Oh, I think the 'myth' is fairly true as far as it goes. It just
doesn't 'go' far enough, sort of.
As in;
It does make the transmitter 'happy'. Since it 'sees' an impedance it
likes, it decides to not
hold back but put out full power. That means that more signal does
reach the antenna than
may have before using that tuner. Which means that the antenna can
radiate more signal.
Does that mean the tuner changes anything about the antenna? It's
input impedance? Or
just the amount of signal that gets radiated. Sort of depends on just
'where' that tuner is,
doesn't it.
People who do know something about how all that stuff works, do know
that this whole thingy
is a 'myth' of sorts. It needs Paul Harvey's, the "rest of the
story", to finish it off. Then it makes
sense.
I seriously doubt if I busted and bubbles here, or repudiated any
'myth'. I'm devastated!

Neither Eham nor QRZ publish official technical opinions of the staff, near as I can tell..... thus the above comments only reflect the opinions of some anonymous contributers. As we all know, regarding antenna theory there is a huge gap in the knowledge of many hams.

Regarding tuners and antennas, isn't the main job of an antenna coupler (tuner at feedpoint) to maximize the efficient transfer of power from the feedline to the antenna? If true, then the coupler (tuner) certainly does have an effect !

I'd never really heard of this myth, but myself, I think the feed
point
is the best place for a tuner if the intent is to match the load to
the
feed line. As an example, if you were using 50 ohm coax, and the load
was in the 1000 ohm range, you would have an overall lower system
loss matching the load to the coax, rather than place the tuner at
the
rig and matching the load seen at the coax to the rig.
With the lower loss ladder lines I suppose it becomes less critical.

I think this is a trick question :-) With a tuner connected to the transmitter by a short length of transmission line to the xmtr output, if we were to literally measure only the forward power component without taking into account the reflected power, a 100 watt net forward output power could consist of 300 watts forward plus (negative) 200 watts reflected ignoring dissipated power along the xmission line for the moment. The forward power meter would not make a distinction between such a mismatch and the desired case of 100 watts total forward and zero watts reflected (or dissipated). One cannot operate the tuner in this configuration for maximum power transfer with either a forward-only meter or one that measure net power delivered (smmation of forward plus reflected). Also, if we did use a forward power meter along with a reverse power meter, a resistive dummy load would appear to be a great antenna when using such a meter combination, just as an antenna that dissipated 100 watts through the insulation system would. The problem with any meter that is used as configured above (placed at the transmitter) is that it cannot distinguish between resistive "dissipated power" along the transmission line and other components, from radiated power leaving the antenna into free space. However, measuring power/current at the feed point gets you much closer to the desired measurement, thus it indicates more correctly an optimum tuner operation. However, it still would not distinguish desired radiated power from ohmic antenna losses such as a might result from a thin gauge wire or heat losses due to high current nodes on the antenna of supposedly acceptable wire diameter.

If we adjusted the tuner for maximum forward power
at the antenna, wouldn't that mean the tuner was
properly tuned for a Z0-match at the transmitter?

I think it would be essentially true for today's FET transmitters that automatically limit output power when the Z0 is not matched, but not for any reason having to do with transmission line theory. You would have to know the output power from the transmitter (assume 100 w) and measure as close to 100 w forward power out at the antenna. Anything less than 100 watts would indicate a Z0 mismatch, again using todays transmitters that throttle down during mismatch as protection. For the theoretical transmitter with no throttle down function, then this configuration would not indicate a proper Z0 matcgh at the transmitter; however, for the old tube driven models, their output stages were much more robust and the mismatch between xmitter and transmission line did not matter so much, especially when they used ladder line, before coax was widely available, and transmission line dissipation was nil.

No, it sounds like it has an effect on the signal that is reaching the
antenna.

The tuner doesn`t change the antenna specification, e.g. gain,
impedance, or pattern.
If you buy a beam antenna you will get this data, and the pattern of the
antenna is most time a free room pattern.

As the tuner is used to match the impedance of the radio to the line it
will effect the power getting to the antenna or the signal received from
the antenna if it is passed through the tuner.

...100% efficient? The only thing I have ever had that was 100%
efficient was my 'Ex', which she pointed out to me quite often. So,
using a tuner that got just a tiny bit 'warm' from it's inefficiency
just wasn't/isn't that big'a deal. When it became noticeably 'warm',
it was because I was trying to match something that just was not very
close to reasonable. Then again, it sort of depends on the tuner you
happen to be using, it's 'usable' impedance matching range, just how
'robust' the thing happens to be built, and what you are trying to do
with it to start with. There are limits. How often you approach
those limits sort of defines how much heat you will see, they make
pretty nice coffee warmers at times ;), not the best idea in the
world, but...
- 'Doc

And just for 'grins', for those who do not 'approve' of using a tuner,
what do you think those gama, delta, and other variety of thingys on
the feed point of that beam are?
(if that don't stir the 'worm soup' up a little, I just haven't had
enough coffee yet. I'm still warming it on the tuner.)

Let's see what is wrong with the following reasoning:

1. Maximum power is delivered to a mismatched load
when the forward power is at a maximum.

2. Maximum available power is delivered to the load
when the source sees its designed-for impedance, e.g.
is Z0-matched.

Why wouldn't the forward power at the antenna be
maximized by a Z0-match at the source while the
tuner is being adjusted?

If the power getting to the antenna is measurable, then
the tuner is causing something to happen at the antenna.
It is doing more than just making the transmitter happy.
After all, a dummy load makes the transmitter just as
happy as a tuner.

The power at the antenna will also be measurable if you decide to bypass
the tuner.
If you have a good match you don`t need a tuner.
But most of the transmitters don`t work correct with a high swr.
Even if they would the best match will get the most power into the
antenna.
The tuner at the transmitter doesn`t change the impedance of the
antenna. It also doesn`t change the gain or the pattern of the antenna.

I the early books I have that is how things were tuned up. The
antenna was dirrectly tapped on to the tank coil. Adjusted for
maximum antenna current. No one had heard of swr meters. Antennas
worked just fine. Today the antenna tuner resonates the antenna. No
antenna tuner? Then no resonanting the antenna. You have to take what
the antenna gives.

If somebody really wrote that "the tuner has no effect at the antenna feedpoint", there are two cases:

1) either he meant to correctly say that, adjusting the tuner, the impedance seen at the antenna terminations - or any other antenna property - does not change (independently of whether the tuner is placed at the transmitter end or at the antenna end). If so, it is just a matter of bad wording, and I would be tempted to say that his english is even worse than my non-mother tongue one

2) or he has a poor understanding of transmission lines and antenna theory

Everyone makes more of a tuner than what it is. If all transmitters were designed to work into very wide loads the tuners would not be needed. Tubes have an impedance of around 1000 to 4000 ohms and must be matched to 50 ohm coax (usual ham antenna design) or some other combination of resistance and reactance. The transisitors must be matched from a very low value (under 10 ohms usually) to a higher impedance.
Many transmitters now in use are for only 50 ohm output (fixed tuning) or a small range (maybe 3:1 for some amps) if they do have an adjustiable tuning.

There are some antenna designs that fall way out of the 50 ohm design inpedance so some way must be made to match the inpedances for maximum power transfer.

Take an amplifier that has a pi-L network built in. If it is adjusted for max power out , and an amp with a pi network with an external L network to match an antenna, what is the differance ?

Cecil;

An antenna tuner does not and can not and will not make any physical or electrical changes to any antenna it is attached to. It will, however, make electrical changes to an "ANTENNA SYSTEM" such that a transmitter or receiver will react to the system more efficiently.

Take a dummy load that exhibits a characteristic impedance of say 75 ohms and hook it up to a transmitter that exhibits a characteristic impedance of 50 ohms. I guarantee that the transmitter won't like it as well as a dummy load that exhibits a characteristic impedance of 50 ohms. All impedances are purely resistive with no inductive component. Place a tuner in the circuit and adjust it for best conditions. The transmitter will think it is looking at 50 ohms not 75.

For more grins, what do you think the "LOAD" and "TUNE" knobs on an older tube transmitter are? They match the output power tube impedance to the antenna system impedance. If you don't believe me mistune a tube transmitter and feel the warmth come from the finals. Have a spare in stock for when you are done.

What is troubling is that the myth seems to be approaching
50% of the posters. If all an antenna tuner does is make the
transmitter happy, it is no better than a dummy load.

Seems to me that delivery of the maximum available power
to the radiation resistance of an antenna is certainly
a physical/electrical change capable, in the extreme, of
melting the antenna.

Consider what a 1kw amp could do to a 40m hamstick used
on 75m when matched with a 1kw antenna tuner.

I think I am trying to say the same thing.

One has to define where the matching system of the final amplifier stops and the antenna system starts. I look at an antenna tuner that is within a few feet of the transmitter as an extention of the matching network between the amplifier device (tube or transistor) and the load which starts with the transmission line.

If the antenna tuner is actually at the antenna, then it is a matching device for the antenna and not in the scope of this discussion.

Is the automatic internal antenna tuner such as in my Icom746 pro really an antenna tuner or is it just taking the place of some knobs that I could turn such as in a Heathkit sb100 ? All that is being done in either case is to match the amplifing device to whatever load is put to it.
I thnk it is just a mater of what someone wants to call it at the time.

Not strictly true. The transmitter output network only matches
impedances to the extent that the transmitter puts out its designed
power.

Dale,

Glad you are happy with the AA-200 but the ability to calibrate an analyzer with standards at the end of a cable or through a filter is IMHO the absolute most important feature an analyzer can have. The difference in accuracy is huge. Additionally the ability to make measurements with a tuned tracking receiver rather than a broadband detector separates the toys from the real equipment in the presence of other RF interference when making antenna measurements. Granted that the absence of a PC is a plus but the larger screen of a notebook PC is a big deal to me as is the ability to capture plots for others to see. I would take the AIM4170 over the AA-200 any day. If you wish, take a look at http://www.bnk.com/w0qe/AIM4170_page1.html for a detailed examination of the AIM4170. I am in no way connected to Array Solutions who sells the 4170.

I'll second that Larry. If you really want to soar add a Bluetooth to
RS232 serial adapter and battery to the AIM. That makes it much more
convenient to use plus it will improve measurement accuracies by
easily having everything floating above ground potential.

Usually inference from an airport radar ASR takes the form of a very raspy 1000Hz more or less burst occuring every 4.5 seconds or so.There is one radar an ASDE that rotates a 60 rpm or once per second. If there is one of these located nearby you may hear the burst once a second. The pattern of the antenna is aimed at the ground hence its name Airport Surface Detection Equipment.At two miles out you could be in its coverage area

Cecil;

How much change in physical length or diameter of wire does an antenna tuner make to an antenna?

Dave

I agree. You adjust the tuner until you have 100 watts measured output. This is an indirect indication of Z0 match at the transmitter. The fact that you can drive 100 watts of real power to the antenna feed point is itself an indirect indication that you must a Z0 match at the transmitter. With a mismatched transmitter, you might be able to drive only 75 watts with a 3:1 SWR or 5 watts at 5:1. You can take advantage of the "information" provided by the transmitter, with reference to its Z0 match condition, by merely observing the maximum available output power.

Obviously that person was an MI5 agent trying to demoralize you into self destructive behaviour. The design is apparently a national security risk and I will predict that for this reason no Western patent office will ever agree to its publication.

Until the State department applies the proper pressure to the host ISP to shut the website down. The Chinese may be experimenting with unwin antennas too, I'm afraid. And they do it with slide rules, not Cray super computers. The Chinese are amazing!

I dont think SDL has an ASDE though I know they were supposed to get
an ASR-11. Im not sure if they got it. The airport does have a REIL
that flashes stobes to mark the end of the runway. Once a second is
probably about the right rate for these. They could eaasily be the
source of your RF interference.

In the above example, it vaporizes the hamstick wire.
IMO, that is quite a change.

The point is, it can be monitored *at the antenna*
thus proving that a tuner does indeed have an effect
at the antenna.

An effect "at" the antenna is not the same as an effect "on" the
antenna. Which did you mean in your OP?

All canards have a kernel of truth in them. My guess is that someone observed that an antenna "tuner" would "tune" a wide variety of oddball antennas to transmitters that were looking for a particular impedance.

Then to simplify matters, someone said "the transmitter doesn't care what is on the end of it, so long as it sees that 50 ohms impedance.

It's a short drive from there to "the tuner has no effect on the antenna".

Actually, it went farther than that:

From QRZ.com regarding tuners:

"The tuner has absolutely no effect at the antenna."

From eHam.net regarding tuners:

"Does nothing. The tuner as the other poster said,
just makes your radio happy."

Cecil;

A "HAMSTICK" antenna has a "MAX" power rating. If you exceed this power rating you will indeed vaporize the wire. Of course this is true of ALL antenna's. Hook up a 50,000 watt transmitter to a 20 gage wire dipole and watch the copper vapor drift off in the wind.
I am currently to lazy to look up the HAMSTICK power rating but you can at your leisure.

Dave

5198. Efficiency and maximum power transfer

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-06 21:12:00 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4849a80e$0$18158$4fafbaef@reader3.news.tin.it>
Source record: 25170

Someone may regard the following question a bit OT, but as it deals with impedances I have considered that the antenna newsgroup could be the most appropriate one where to post it.

Let us regard a transmitter as an ideal RF generator with a resistance in series. It is well known that, for maximum power transfer, the load resistance must be equal to the generator resistance. Under such conditions efficiency is 50% (half power dissipated in the generator, half delivered to the load).

To achieve a higher efficiency, the load resistance should be made higher than the generator resistance, although this would turn into a lower power delivered to the load (the maximum power transfer condition is now no longer met). This can be verified in practice: by decreasing the antenna coupling in a transmitter, one obtains a higher efficiency though with a lower output power.

That said, now the question.

Usually, when a transmitter is tuned for maximum output power, efficiency results to be higher than 50% (typically >60% for class-B, >70% for class-C). This would seem to contradict the above cited fact that, under maximum power transfer condition, efficiency is 50%.

Pertinent comments are welcome.

Simple: a transmitter is not an ideal voltage source with a resistor
in series.

I'm playing with a switching power supply design that delivers about a
kilowatt at 100 volts. The output is designed specifically to have a
negative resistance, so the output voltage increases as the current
drawn increases. The output dynamic impedance is about -1 ohms
(adjustable, actually). The linear model is a 100 volt battery in
series with -1 ohms. With an 11 ohm load, I get 10 amps load current,
with the battery thus delivering 1000 watts, the load dissipating 1100
watts, and the -1 ohm resistance dissipating -100 watts. Which shows
the absurdity of thinking of a dynamic output resistance being
anything like a real resistance. In my switching supply, I can adjust
the dynamic output resistance between a small negative value and a
rather larger positive value, with very little change in efficiency.

Although transmitters MAY have dynamic output resistances similar to
the recommended load resistance, that's not a necessary condition, and
has little to do directly with efficiency.

Cheers,
Tom

In addition to Tom's comments, an RF Power Amplifier's efficiency is defined as (Pout/Pin)X100%. Pout is RF and Pin is usually DC. So if you pump 1000 watts DC in to a class B RF amp and get 600 watts rms out you are 60% efficient. Your model of a Voltage Source in series with an internal resistance does not apply here.

The maximum power theorem gives conditions where power in the load, is equal to internal power in the generator. Not always a good idea. A 50HZ generator capable of Megawatts of power would dissiapate 1/2 in the generator and 1/2 in our houses if they designed them to conform to the MPT. The 50HZ generators would melt. Utilities design their Generators to have nearly 0.0 ohms internal impedance.

Good question.

The point is that if an amp is equipped with foldback,
it probably cannot vaporize a severely mismatched antenna
without the aid of an antenna tuner.

The maximum power transfer theorem only applies to
linear sources. What is the linear source impedance
of a class-C amp?

Dear Tom K7ITM:

Thank you. Thank you. Thank you.

Let us put away forever the idea that a normal transmitter fits the
passive, linear model of an ideal voltage source in series with an actual
resistor.

The active device(s) in an amplifier (tube, BJT, FET, ...) needs to see
a certain impedance (at a given frequency) in order to have desirable
performance characteristics. Too many have extrapolated from that
information (found in data sheets for the active devices) the conclusion
that the active device has an internal Z that is the complex-conjugate of
the load Z.

The wording found in another string of messages communicates the right
idea. A normal transmitter "wants to see" a certain Z. That Z is most
often 50 ohms.

RIP 73, Mac N8TT

P.S. An IEEE paper explored this issue in the last year.

This has been a good example of a common pitfall in modeling. The error made in this case was to attempt to apply an unsuitable model (a voltage source in series with a resistance) to a system to be modeled (a transmitter). As the OP showed, the attempt leads to an impossible result. The classic example of this is the "proof" that a bumblebee can't fly, based on a flawed model and immediately shown to be false by simply observing that they do, indeed, fly. Yet we see people falling into this trap daily, not only in modeling electrical circuits, but also in modeling such diverse processes as human behavior, economic systems, and roulette wheel numbers.

Unfortunately, the bad results of applying unsuitable models aren't always so obvious as they were here. So it's always wise to check to see if the model fits before putting faith in the results.

The source resistance appearing at the output of either a Class B or C amplifier is R = E/I, where E is the
peak voltage at the output terminals and I is the peak current at the output. Or RMS values can also be used.
Since E/I is simply a ratio, R is also a ratio. And we know that a ratio cannot dissipate power, or turn
electrical energy into heat, thus the output resistance R is non-dissipative. I have made many measurements
that prove this. It is also the reason why reflected power does not dissipate in the tubes, because it never
reaches the tubes. The reflected power simply causes a mismatch to the source, causing the source to deliver
less power than it would if there were no mismatch. The input at the pi-network in the xmtr is non-linear, but
the fly-wheel effect of the network tank isolates the input from the output, resulting in a linear condition
appearing at the output. Except for a very slight deviation from a sine wave due to a small amount of harmonic
content, the voltage E and current I at the output are essentially a sine wave, which one can easily prove
with a good oscilloscope, proving the output to be linear. I'm speaking for tube rigs with pi-network tanks,
not for solid-state rigs.

I nearly forgot. The only dissipation in the amp tube(s) is due to the filament-to-plate current as the
electrons bombard the plate. The efficiency is determined by the ratio of the DC input power to the RF output
power. The maximum power is delivered when the load resistance equals the output resistance R of the source.
But since resistance R is non-dissipative it is not a factor in determining efficiency. The only factors in
determining efficiency are the RF output power and the dissipation in the tube caused by

the electrons
striking the plate. The non-dissipative output resistance is the reason Class B and C amps can have an
efficiency greater than 50 percent. If the output resistance were dissipative it would be the determining
factor in efficiency, which could never be greater than 50 percent if the load resistance was equal to the the
output resistance.

A report of my measurements will soon be available in Reflections 3, from measurements taken since those
reported in Chapter 19 of Reflections 2.

Cecil, if I send you a copy of the new chapter that has the report of my newer measurements do you have any
way to make it available to the guys on this thread?

Actually, the AC power distribution system from alternator down has a
manged substantial equivalent source impedance.

The source impedance serves to limit fault currents, which reduces the
demands on protection devices.

Sure, the network is not operated under Jacobi MPT conditions, but neither
does it have near zero source impedance.

But your statements are not true. The model you propose for a transmitter
does not apply in general. Whilst it would be possible to build a
transmitter like that, most transmitters that hams use are not built like
that.

So... it is a loaded question of a type, a question premised on a
falsehood.

If the equivalent source impedance is not important, ie it does not need
to be fixed by the design, there here is an analysis.

If you take the case of a grounded cathode triode in class C with a
steady signal, the conduction angle is usually somewhere around 120°. The
anode current waveform is a little like a truncated sine wave, but even
for the range of grid voltages where anode current is greater than zero,
the transfer characteristic is not exactly linear, and the wave will be
further distorted.

If the nature of the anode load is that it is some equivalent R at the fundamental and zero impedance at all other frequencies, the power output can be determined by finding the fundamental component of the anode current waveform, squaring it, and multiplying it by R. The input power is the average anode current multiplied by the DC supply voltage. Efficiency is OutputPower/InputPower. By varying the grid bias, drive voltage, load impedance and supply voltage for a given triode, different efficiencies will be found, and the maximum could be well over 80%.

Nothing in this approach to design attempts to fix the equivalent source impedance, the design is performed without regard to that characteristic.

Nevertheless, some argue that the output network performs magic and achieves source matching naturally without designer intervention, and does this irrespective of parameters like the dynamic anode resistance, and the effects of feedback (such as cathode degeneration in grounded grid amplifiers which in turns depends on the source impedance of the exciter).

Owen

If you want to explore this approach to design, I have implemented a spreadsheet which in turn implements the methods described in CPI/Eimac's "Care and Feeding of Power Tubes" it is described and can be downloaded at http://www.vk1od.net/RFPATPC/index.htm . The spreadsheet is populated with the example 4CX20000 in Class C from the above publication.

The spreadsheet calculates the anode current wave form from an interpolation based on a number of points from the published characteristics, and calculates the fundamental component of anode current using an FFT. It then calculates anode efficiency and overall efficiency given operating parameters.

Not really sure I agree. A multi-megawatt 60HZ generator by necessity
has near zero source impedance. The ones I am familar with require
forced air cooling on their output buses. If you are pumping out Mega-
watts, then any non -zero source impedance results in serious heat.

Gary, you use the terms impedance and resistant as if they were
equivalent.

Alternators have a designed value of leakage reactance, and they also have resistance. The combination make the equivalent source impedance, and it is sufficient to limit fault current to something typically in the range of 20 to 50 times the rated output current.

Transmission lines and transformers in the transmission and distribution networks are usually designed in the same way.

It is not zero, and it is not purely resistive. Most supply authorities would not allow you to connect a capacitive load (a leading PF load), so another concept, conjugate matching (in the Jacobit MPT sense) is also not practiced.

Understanding the electricity network does not really give an insight into a typical ham radio transmitter, they do not share the same design objectives.

Hmmm. Past experience suggests my Russian 5KW amp has no "foldback." I hesitate to think other experience the same--but, judging from some signals, it is quite likely!

BUT! Very happy with the SDR!

Good to see that everyone agrees that a generator with a resistor in series is an unsuitable model for an RF transmitter.The easy part of the work is done!

Now the more difficult part. As, by the Thevenin theorem, any complex circuit comprising resistors, voltage generators and current generators is equivalent to a generator with a resistor in series, evidently the transmitter model must comprise elements other than just resistors, voltage generators and current generators.

Can one suggest how such a model looks like? (even a plain one, that does not take into account second- or superior-order effects).

Hello Walter,

thanks for your explanation.

I remember having read your excellent articles on QST magazine many years ago, in which you also explained, among many other things, why reflected power cannot dissipate in the final stage of a transmitter.

I am not at all opposing your explanation of "non disspative resistance" (on the other hand how may I contradict a person named Maxwell, hi), but I have some difficulties to appreciate it.

In my understanding resistance just means that current and voltage are in phase.

There are two possibilities for this to occur:

1) dissipative resistance. Example is a pure resistor, in which power is converted into heat.
2) non-dissipative resistance: Example is a DC motor, that converts electrical power into mechanical power. An ideal motor would convert all absorbed power into mechanical power, producing no heat

But I am unable to see how the second case could be fitted into the transmitter model.

Thanks and 73

The maximum power theorem gives conditions where power in the load, is
equal to internal power in the generator. Not always a good idea. A
50HZ generator capable of Megawatts of power would dissiapate 1/2 in
the generator and 1/2 in our houses if they designed them to conform
to the MPT. The 50HZ generators would melt. Utilities design their
Generators to have nearly 0.0 ohms internal impedance.

Good question.
Gary N4AST

Whay you write is perfectly true.

To maximize efficiency, the ratio between load resistance and generator
resistance must be as high as possible. That is the reason why the internal
resistance of the Megawatts generator you took as an example is always made
extremely low (very little power is so dissipated within the generator).

Those generators however do not operate in the maximum power transfer condition
(generator resistance = load resistance). As a matter of fact one cannot
decrease the load resistance below a certain threshold because of the generator
power delivery limitations.

In other words the generator can deliver the maximun power it is able to
deliver, but not under maximum power transfer conditions. Never mind, what is
important is that efficiency is good!

Hi Tony,

The reason a Class B or C amplifier can have efficiencies greater than 50 percent is because the output source
resistance at the output of the pi-network is non-dissipative, as I said in an earlier post. I realize this

phenomenon is somewhat difficult to appreciate. However, I have explained it, and proved it with measurements
reported in Chapter 19 in Reflections 2. I have explained it further in an addition to Chapter 19 that will
appear in Reflections 3, which has additional proof from measurements made since the original Chapter 19 was
written.

This addition to Chapter 19 is Chapter 19A, which I asked Cecil to put on his web page for all to see. Just
scroll down to Cecil's post to see "Chapter 19A from Reflections III", and double click on the url. You will
see the entire Chapter 19A. Apparently you don't have a copy of Reflections 2, so I'm going to email you a
copy of the original Chapter 19. I hope these papers will help in understanding why the output resistance of
the pi-network is non-dissipative.

Source record: 25199

I have just put up an 80 Meter End Fed Flexweave wire. Its about 63 feet long and fed direct with 50 Ohm coax at the far end of the garden. The shield is connected straight down to a ground earth stake at this point and it is tuned for 3.700 MHz. It receives better than any thing I have used so far, but it is very death on 40 meters. Almost unusable.

Is there a reason for this?

The antenna is only up at 20 feet and my old G5RV is only 6 feet off the ground at the moment and receives far better on 40 meters than the End Fed wire.

I believe you have mis-stated the Thevenin theorem. First, it applies only to linear circuits. Fine -- over some narrow range at least, a transmitter does indeed look like a linear circuit. But more importantly, it describes ONLY what you observe at an external pair of terminals, with no other connections, NOT what goes on inside the "black box" containing those elements you mentioned.

A very simple example is a voltage source (a perfect battery) and two resistors in series across the battery; the external terminals for this example will be at opposite ends of one of the resistors. Let's say the battery is 2 volts and each resistor is 2 ohms. That will look like a Thevenin equivalent 1V in series with 1 ohm. Note that it also looks like a one amp source in parallel with a one ohm resistor. But it does not behave INTERNALLY like either of those. Consider also the same internal circuit, except drop the voltage source to 1V and add a 1/2A current source across the output terminals, polarity so that there's no drop across the resistor between the voltage and the current source (with no external load). Now figure the internal dissipation for each of those two cases, with no load, with a 1 ohm load, and with a short-circuit load.

Cheers,
Tom

5232. Re: Efficiency and maximum power transfer

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-08 18:47:03 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <JrCdnR01Yp20tNHVnZ2dnUVZ_sednZ2d@easystreetonline>
Source record: 25054

There's a common misconception that, for a linear circuit, the maximum efficiency and/or power available from a voltage source occurs when the source resistance equals the load resistance (or, more generally, when they're complex conjugates). But this isn't universally true, as I'll show with a simple example.

Suppose we have a 100 volt perfect voltage source in series with a variable source resistance, and a fixed load resistance of 100 ohms. If we make the source resistance 100 ohms, the source delivers 50 watts, 25 of which are dissipated in the source resistance and 25 watts in the load. The efficiency, if you consider the source resistance dissipation as wasted, is 50%. But what happens if we reduce the source resistance to 50 ohms? Now the source delivers 66.7 watts, of which 22.2 is dissipated in the source resistance and 44.4 in the load resistance. The power to the load has increased, and the efficiency has increased from 50 to 66.7%. The efficiency and load power continue to increase as the source resistance is made smaller and smaller, reaching a maximum when the source resistance is zero. At that point, the source will deliver 100 watts, all of which is dissipated in the load, for an efficiency of 100%.

The well known and often misapplied rule about maximizing power transfer by matching the source and load impedances applies only when you're stuck with a fixed source resistance and can only modify the load.

Yes there is- it's a half wave long on 40M which implies voltage feed and a
VSWR in the 60--80:1 range.

What seems to be overlooked here is that the source resistance at the output terminals of the pi-nework in Class B and C amplifiers is non-dissipative, which is the reason they can be loaded for delivering all available power for a given grid drive, and still have efficiencies greater than 50 percent. One of the myths circulated for years, and still prevelant, is that the reason for Class B and C amps to have efficiencies greater than 50 percent is that the load resistance must be greater than the source resistance. Tain't so.

I've proved the above to be true with extensive measurements using laboratory grade instruments. Reports on those measurements are reported in Chapter 19 in Reflections 2, and additional measurements taken after Reflections 2 was published are reported in Chapter 19A, to be published soon in Reflections 3. This additional chapter is listed here in the rraa for your information. If anyone is interested in reading Chapter 19 in Reflections 2 it appears in my website at www.w2du.com.

Hello All,
I am building a DL6WU Yagi for 2 metres and am wondering if 1/4 inch stainless steel tube would be okay for the directors and reflector. I have been given some so it would save me from having to buy aluminium. I will still use aluminium for the folded dipole and for the boom. Any thoughts would be welcome.
Cheers

It will probably be a bit lossier than using Al but my first Yagi on 288 MHz(in the early 60s)was made out of 8g fencing wire and it seemed to work reasonably well. Try the evaluation version of Eznec - I think you can specify the material.

Just checked - tried a 6m yagi and with Cu elements, gain is 9.64dB With
SS elements, gain is 9.41 dB

>
>Dale W4OP
>

The question is, what are the consequences of having such a high SWR? It
all depends on how much attenuation the coax has. If the coax was
lossless, there would be no signal loss, regardless of the SWR.

For many years, I have been an advocate of this 'far-end feed' type of
antenna. Its great advantage is that it greatly reduces the amount of
local interference it receives (and creates). Also, all the essential RF
grounding is at the far end. You don't need an RF ground in the shack.
The shack is RF-dead.

Ideally, you would use a tuning/matching unit at the antenna feedpoint
but, provided your coax has adequately low loss, you can get away with
having the tuning unit at the shack end of the coax. It's surprising how
well this works - especially on the lower frequency amateur bands.

For reception only, it might be worth while considering fitting a
matching transformer at the antenna feedpoint. These typically have an
impedance ratio of 9:1. The essential purpose is to prevent extremes of
impedance mismatch between the antenna and the coax. Below, I have
appended some information from 'RHF', one of the contributors to the
rec.radio.shortwave newsgroup. Note that these devices are NOT baluns!

My present antenna is about twice the size of that described. It's about 120 foot inverted-L, at around 25 feet. The coax length is about 90 foot. I can tune it up from 160 to 10m. It certainly seems lively enough up to 20m.

As I said, you do need really good low-loss coax. CATV trunk cable is pretty good, if you can lay your hands on some. Don't worry about it being 75 ohms.

Depending on frequency, you are going to get quite a variety of weird impedances at the shack end of the coax. What you get will be whatever the feed impedance of the antenna is, but transformed by the length of the coax, and influenced by its attenuation. In the example of the Flexweave wire, the antenna is around a halfwave long, so the impedance is very high. However, the coax will be (guessing) 40 foot long, which, allowing for a velocity factor of 0.6, will also be a halfwave at 40m. The impedance at the shack end will therefore be very high, which may not suit the receiver. You will certainly need a matching unit to transmit.

Finally, having used the 'tuner-in-the-shack' method for around 30 years, in my old age I am considering investing in one of the automatic remote tuning units (such as the SG-230). However, one slight disadvantage is that, in order to work, they need to be fed with RF, so are not suitable for SWL-use only.

From 'RHF' in rec.radio.shortwave (29 March 2008)

Some people as a result of the coining of the Word "Balun"
[Bal-Un] for Balanced-to-Unbalance Matching Transformer :
Also like to use the Word "Unun" [Un-Un] for the Unbalance-
to-Unbalanced Matching Transformer.

"Balun" a specific Contraction becoming an inclusive Buzz Word
relegated to commonly misused technical Jargon.
http://en.wikipedia.org/wiki/Balun

Most of these Matching Transformers used between Single Wire
Antenna Elements and Coax Cable are 'not' Baluns but Ununs
since the Match-up an Unbalanced Antenna Element with an
Unbalanced Coax Calbe feed-in-line.

Many Manufactures have come-up with Trade Marked Names

Hi Dale,

Does this only apply to 1/2 wave long end feds only?

Does this apply to any frequency?

The maximum space here is only 66 feet at best.

What options am I left with that would work for 80-40 meters?

I have a question about traps. I read yesterday that traps should not be
tuned to resonance of the wanted frequency. If I constructed a homebrew trap
for say 7.1 MHz.
How far away from this frequency should I tune the trap?

Should it be tuned higher or lower?

I did search the internet, but I could not find any info on whether its best
to setup the trap higher or lower than the wanted frequency and by how much.

Andy

Using an 11 el DL6WU at 144.2MHz and 10mm elements, EZNEC gives gains of 14.31 dBi for Al and 14.22 for SS. With 5mm elements, it's 14.54 for Al and 14.37 for SS.
I used a figure of 7e-7 ohm-m for the resistivity. Most stainless steels range from 5e-7 to 7.4e-7 ohm-m.
3dB does seem excessive.

Certainly it changes the impedance looking into the tuner
input and that has an effect on the entire antenna system.
The forward and reflected voltages, currents, and powers are
at their maximum values when the tuner achieves a Z0-match.

> resistance must be greater than the source resistance. Tain't so.

Walt - what is your thinking on the point that untuned, solid-state amplifiers also can have PA DC-to-RF power conversion efficiencies of 70% or more at the device level?

In fact the solid-state, analog FM broadcast transmitters supplied by Harris Corporation and others need no tuning to produce their rated output power into a 1.3:1 SWR or less, anywhere in the FM broadcast band 88-108 MHz. Even the harmonic filter needs no changes, and maintains harmonics at -80 dBc or better. They are frequency agile, and can be reset from one carrier frequency to another, anywhere in the FM band with a transition time of a few seconds

The overall AC input to r-f output efficiency of these transmitters exceeds 60% (includes the exciter, control system, IPA, and cabinet fans).

True, but the value of Z0 of the transmission line has a
large effect. Let's say we are feeding one of those 5000
ohm antennas. The SWR on 50 ohm coax would be 100:1. The
SWR on 450 ohm ladder-line would be 11:1. Even if the coax
had the same matched-line loss as the ladder-line, it would
still be much lossier than the ladder-line - and much more
expensive.

Lots of technical ways but as a first guess, TV ribbon (ladder line) is
300 ohms and the conductors are spaced about 8.5mm
450 ohm ribbon has wider spacing.

Tune it for lower than the operating frequency to
minimize trap losses. The point to shoot for is
the maximum inductive reactance point which is
at a lower frequency than the parallel resonant
resistance point. How much lower depends upon
the Q of the trap.

I have nothing here to measure the Q of the trap.

Is there another way of working out the correct frequency needed for the trap?

The traps are made from RG58 C/U. I think these are a low Q but I'm not sure.

I think that the secret is to make sure that antenna is not exact
multiples of a halfwave. This prevents the SWR being absolutely sky-high
- say, 'only' 20:1, worst case. The proviso is certainly that the coax
should be as lossless as possible. I'm happy to lose 3 or 4dB in the
interests of simplicity and good EMC. It's mainly 160/80/40 which I'm
interested in. There's just a load of foreigners on the higher bands!

Some time ago, I did some (more) Smith Chart guestimation with the
object of trying to find which 'magic' inverted-L antenna lengths would
present 'reasonable' impedances on all (or most) of the amateur bands up
to 30Mhz. [Many years ago, I reckoned that around 185 feet was a good
length.] However, my recent efforts ended in dismal failure. In the
meantime, I will continue in complete ignorance, and use my antenna as
it is, accidentally having the occasional QSO and causing no obvious
interference problems. But, after all these years, I might treat myself
to an automatic tuner for the far end of the coax.

Sorry, I would just be guessing. I made my 40m traps
resonant on 7.4 MHz and they worked well over the
40m band. But I never made any measurements or A/B
comparisons.

Max,
While there may be some degradation in gain from using stainless steel, would it really make that much difference? I think the 'biggy' is that you already have the stainless steel and would have to find the aluminum. Maybe the next 'biggest' thing would be making electrical contact between sections of that steel? A tenth of a dB loss just ain't no step for a stepper...

> Alan VK2ADB

Apparently Brian used iron as the model material, which of course is magnetic. Skin depth is reduced, and therefore RF resistance increased, by the square root of the permeability. So if the iron model's permeability is, say, 100, it would increase the effective resistance by a factor of 10.

Some stainless steels are magnetic, some are not. The magnetic ones have much higher RF resistance than the non-magnetic ones for the above reason.

I know this question was directed to Walt, but I'd like to mention that
I've designed and built solid state class C amplifiers at the 5 - 10
watt level which have measured efficiencies of greater than 85%.

Judging from this response, I assume you think I have a problem with the
link. I do not.

I do have a problem with several sentences in the web page. I recently
watched "The Ghost Particle" on Nova. Some of the Neutrino particle's
behaviors stated on Art's page just did not jive with Nova's program, so
I looked up a Wiki definition of the Neutrino. The Wiki follows Nova's
description of the Neutrinos Particle, hence the post:

Uh, no ...

But, you do give yourself away with your text and its' direction. Your problem is a very simple one; you see yourself as the center of importance and my focus in any exchange of text you and I have had. Rest assured, you are in error--at least where it involves myself.

Most often, I say what I mean and mean what I say.

Your tea leaves, crystal balls and examinations of my text are likely only lead you to draw more erroneous conclusions, and are likely to lead you further astray of my meanings and intentions--given your mindset ...

Or, in summary, if you desire a childish conflict, search for those of a like mind and purpose.

5272. TV Antenna.....Please Help....

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-09 18:14:06 UTC
From: Solomon_Man <cmgray74@gmail.com>
Message-ID: <925c0d83-b760-4fcf-a2e9-90a5fb94fc04@l42g2000hsc.googlegroups.com>
Source record: 25094

All,
Some History...
My home, previously owned by my parents, has approximately a 30' Tower and has a channel master antenna (whats left) attached to it. It was used for TV/Radio reception originally. If I remember correctly it was around a $100-$125 bucks for the antenna alone and had a range (supposedly) of around 100-125 miles. I live in the suburbs of Toledo, Ohio. The current antenna had a bumpy start when the original installer (a professional) dropped the antenna from about 25 feet up. A few things were dented and broken. It was cleaned up and then the antenna was still installed. The decision was based on the fact that we are in the surburbs and the antenna was an overkill. From memory the unit had a cracked chunk of plastic and a bunch of dented\bent rods. We had no problems with the unit reception wise so it really did not affect its use. The antenna tower was second hand, but the rotor motor, antenna, all wiring and the control box was new. The rotor motor and its control box since installation has been used maybe 3 times. Once installed we had really good reception and picked up Detroit,Toledo,Some Cleveland (Good Day) and some single channel in Indiana. I do not remember any Columbus channels as some channels were really fuzzy. (not sure if it was columbus or not)

Any Ways...Fast Forward ...a few years.....

Then about 6 yrs ago, a year before I took posession of the house and when my parents were cable TV subscribers, the antenna broke basically in two and a large chunk of the antenna came crashing to the ground. The remaining antenna chunk and tower is still standing to this day. Its a eye sore to say the least.

My goal is to replace the antenna and I need some advice.

Would you keep the tower? The only thing I can see wrong with it is that it has a large bunch of vines growing up the middle. There is little to no rust. The vines have been recently chopped down but the higher section of vine is still intangled in the tower. I have tried to climb the tower and got about 15 feet up and it swayed a little so I came down. I am a little to heavy, or chicken, to be climbing towers. The vines should not affect climbing the tower.

Or would I be better off/the same to get a roof mount antenna?

I liked the range of the previous antenna, so what would everyone suggest for an antenna with a range of around 100-125 miles that could be mounted to a 30 foot tower and will be used for radio and TV reception I have made a few phone calls and everyone locally pushes

the Channel Master but I am little nervous about having to have to do this every 7-10 years based on the last antenna. Has anyone had better experience with Channel Master?

As its been used like three times, would you replace the rotor motor?

What should I expect to pay to have a new antenna and rotor motor installed in my home?

Anyone know a good antenna dealer in the Toledo, Ohio area?

Thanks,
Chris

Really? That is the problem? Huh, never would have seen that one coming!

OK, let me expand and give greater detail on "the meaning" of those words, by example--at least where they involve myself.

1) Say a host offers me a Jim Beam on ice at a social event--I have replied, "That works for me!" (my favorite drink is a Vodka Collins!)

2) A kludge is thrown together to patch a nasty little glitch in a computer program (a real fix will be done later), I have replied, "Works for me!"

3) Someone offers me a website which provides the data/information I have requested, they have made a slight error which I wish to, and mostly overlook--so, playing down the importance of such, I reply, "Works for me ..."

4) The wife purchases a new "nightie", I have been known to reply, on occasion, "THAT WORKS FOR ME!" <EVIL GRIN>

5) etc ...

Again, I feel you are too focused on your "perceived importance" or else my desire for conflict, I assure you, I am unhindered by such.

Perhaps and far too often, one is given to find what one searches for. Let's control the direction of these endeavors. And, in such light, I am pleased you asked for clarification, so my intents would become known to you--hopefully, you will accept my stated intent.

Regards,
JS

Hello Richard,

Sorry, Richard, I have no knowledge of solid-state untuned amps, so my thinking on them is zero, nada. As you'll note, all of my discussion on the subject concerns only tube amps with a pi-network output, and I've specifically stated these conditions.

If you've read Chapter 19 and its addition as Chapter 19A, do you agree with my position that the output resistance at the output terminals of the pi-network is non-dissipative?

Walt, W2DU

If you're going to use a tuner it doesn't matter whether it's 300, 450 or 600
ohms.

Yes I rechecked it with 7e-7 ohm-m and 0 permeability and got a lot
better results. Moral here is don't use iron wire for antennas .

Wow, does not look that way from here.

1)Art offers a web site address which I go and look at because for the life of me I do not understand why he and other have such dislike for each other. I find the site to state things about Neutrino's that is contradictory to what I just learned.

2)I post a link to web page that contains information about what I understood a Neutrino to be and a corrected link to his site. The post is terse but in a way that shows that I disagree with his information.

3)Helmut Wabnig posts a response indicating that Art's page is silly.

4)You post a response correcting the URL.

5)I post a response to you indicating that the URL is not in question, but the information on Art's web page is, and why I feel so.

6)I am called self important.

7)Feeling I missed something I ask what you meant by the question "Work's for me".

8)You respond that you were correcting the URL.

The only thing I can figure is since I was viewing only unread posts, the tree indicated you were responding to me. This is why I responded to you that the error in the URL was not why I was responding to Art.

I believed you were responding to me, and you thought I was responding to you at point #4.

Hmmm....

Thunderbird BTW.

You would probably need to replace the twinlead as well as the antenna.
The next time you see a Radio shack, you might sneak inside and ask about TV antennas.
Or they probably have a web site. with prices
Yeah - they do - click on this link...

I used a dozen turns of RG58 on the same core, and achieved XL ~= 200 ohms at 14MHz for a Cushcraft A3. RG142 is about the same OD, so you should be able to fit that many turns on the toroid. If you want more XL, stack two (or more) toroids.

John, "As always" you are posting pure BS in your constant search to look for a petty argument in which your persona can then pose as one who prefers to take the high road. If you really prefer to take the high road, then do so; don't try to preach to everyone else that this is what YOU do, therefore the rest of us should do the same. Sorry "John" but the road you take is neither high nor low. Your persona, like your usenet id, is a mere abstraction which explains your fondness with Art's fantasy antennas

Dan and Bryan,

200 ohms seems too low. I just wound 10 turns on a FT-240-61 core,
single layer occupying about 70% of the core and made the following
measurements of choking impedance on an HP8753 network analyzer in a
calibrated test fixture. The choke was mounted clear of any metal.

14MHz: 220 + j2850
21MHz: >20K
28MHz: 895 - j3.9K

The 10 turns were parallel resonant at 20.9MHz and the calculations for
10 turns would be ~18uH at low frequencies.

The above choke would be very very good from 20 thru 10m.

73,
Larry, W0QE

Chris,
Seven to ten years ain't bad for the life span of a TV antenna really. Some might last longer but most are ready for replacement/ repair in that time period.
You might give a thought to the cabling when replacing that antenna. Might not have to replace the rotor, but certainly wouldn't hurt to replace it's control cables. If it isn't used, why not just remove it? Then again, you might want to see if you can't receive more stations by swinging that antenna before doing that.
Best advice for finding a 'cost affective' bargain would be to shop around, see what things are going for. Nothing wrong with being frugal, but don't expect miracles no matter what the price.
If quality reception is the goal, I also think you might consider keeping that cable or sat' system, rather than going back to an antenna. Getting rid of the tower, rotor, etc, shouldn't be a problem at all, too many of them hams around for that! Something on the order of, "You get it down and out'a here and you can have it!", will make your ears pop from the air slamming shut when it disappears.
- 'Doc

Be wary of putting too many turns on, especially for a lower loss mix such as 61.

As you put more turns on, the series R and X of the ideal choke increase, but the distributed capacitance also increases. Self resonance isn't so bad for lossy mixes, because the impedance is still fairly high where the total ZX passes through zero, but with a lower loss mix, you may find choking impedance at frequencies a bit above resonance become unacceptably low.

It is really hard to assess this with spot frequency measurements.

To start of with, I would wind as many turns as you can fit with a inter-turn spacing equal to the coax diameter... in other words, half the turns that you could get by a completely filled single layer, then make sure the turns are evenly spaced.

There is a cross over winding configuration used which its supporters argue increases the self resonance frequency. I haven't seen that happen reliably in my experiments, rather the reverse happens more often (ie that it reduces the self resonant frequency a little).

Owen

Sayeth Art,

>2. All dynamic particles have a degree of torque or spin which aids directional movement within the universe.

The universe is a big rifle.. I wonder what the rate of twist
is.... :/

>Static particles has a less spin which allows a scattering of movement after ejection from the sun’s arbitrary >field to various parts of the universe and beyond, included what is known as the milky way constellation.

How can a static particle move, much less have spin? I'm confused..
I guess it's because I don't have the vast education that Art had in
some
past life. I say past life, because judging from most I read, he must
have
forgotten everything he learned.. Either that or he just wants to be
different
and proclaims all prior art as something to be ignored.
I do agree to his statement as to the existence of the Milky Way.
But... even a redneck dummy like me knows it's a galaxy, not a
constellation. I guess his astronomy learnin was in a past life

also...
I like to look at it, but I can only see it well when I'm out in the sticks.
You generally can't see the Milky Way in the city limits of Houston. Too much light pollution.

But lets ponder a "static" particle that decided to propel itself across the great lawn of outer space all the way to the Milky Way. I wonder what will happen when these "static" particles that decided to move, clash with the like particles being ejected by all the zillions
of stars in the Milky Way galaxy. Will they collide with a mighty flash of light? Will they taunt each other to fight? Would they combine
to form "Unwin particles" which begin to twist in a opposite direction?
Maybe we could name these "Articles" in Art's honor. Well, in Art's case, I'm sure he would prefer honour. I think that would be the UK version.
Makes my head swim considering all the possibilities of this "New Science"...

So sayeth Art...
The millions of particles after ejection travel in a straight line
with zero gravitation effects on its movements all of which are
following each other in a particular sequence that is reflective of
the oscillations applied to the radiator, bouncing off of the
arbitrary outer surfaces of the earth until they impact and rest on a
diamagnetic surface' which by virtue of its mechanical properties
accepts the arrival of the airborne particles in the same progression
that they left the radiator such that a mirror image of oscillations
from the sending antenna is imparted to the receiving antenna to
complete the communication process.

How will these millions of particles travel in a straight line?
In another paragraph you said they had a twist?
I'm confused. Enlighten me, Obe-wan Kenobe.
You're our only hope.
I wonder about the resting of these particles on surfaces
of virtuous mechanical properties.
What happened to them? All tuckered out?
Decided to stop for gas and some choke and puke
food?
Or maybe they were enticed by some hottie female

particle that danced seductively along this surface
of virtuous mechanical properties?
The rest kind of reminds me of looking at a picture
of a picture in a picture in a picture, etc ad nausium.
Fascinating this new science is.

So sayeth Art..
Of course with modern day computer programs of the optimizer form if
we move away from standard physics and not predetermine a planar form,
the computer program which is based on Maxwell's laws will include the
anti gravitational field(4) which as predicted by applying an
extension to Gaussian law will show radiators where the majority are
resonant such that the array in it's entirety is in equilibrium and
certainly not parallel to the earth's surface!

What other physics would you suggest? Substandard physics?

So sayeth Art..

We can now state that:

A RADIATOR CAN BE ANY SIZE, SHAPE OR VARYING ELEVATIONS AS LONG AS IT
IS IN A STATE OF EQUILIBRIUM.

What will be the efficiency of a 1 inch long Unwin antenna that
is used at 1.890 mhz? This may or may not be a trick question.

So sayeth Art...

7. Ground planes are a means of placing a fractional wavelength
antenna into equilibrium form where the operating period includes
other actions within the system but outside the confines of the
radiator itself.

I'm impressed. That just craps all over everything I ever learned
about
ground planes.
Art, you *are* truly gifted.
I nominate you as the cover boy of QST for the April 09 edition.

So sayeth Art...

However, all is not lost since the tank circuit and the pendulum
mechanism produce identical oscillations for a particular period.

Whew! that's a relief.. Would this be kind of like a perpetual
cuckoo clock? Or would this resemble the identical amounts
of motion that the little dancing people do when it's O-clock?
"Note" Many cheap cuckoo clocks only have a small bird that
jumps out of the little door near the top.
But some higher level cuckoo clocks have little dancing people
that dance around in a perfect circle. Being as they are mechanically
affixed to some kind of plate, I assume you could say these
dancers are in a state of equilibrium..
This new science is making me hungry... I need a fig neutrino...

So sayeth Art...

With reference to the now smaller radiators, the new definition for a
radiator can now be achieved by two Meander type circuits on different
levels and connected such that the combination is in equilibrium.

You could patent that one as a Meanderlibrium antenna.
I tried a fig neutrino.. Had no taste at all.. I've seen shoe boxes
wrapped with 22 gauge wire with more flavor to them..

> Brian Howie

So sayeth Art..

Derived oscillations for a 12 inch diameter close contra -wound
helical antenna in equilibrium with a length of 12 inches Wire used is
approximately 2 thousand feet of
19 a.w.g magnet wire and without the implementation of a variometer or
a progression of jumpers to bring continuity to the SWR in the less
than 3:1 level of impedance.
Note. No tuner losses are encountered and the antenna in equilibrium
is placed on top of a tower without the need for a ground plane where
it follows the rules of a traveling wave antenna.

I had thought it followed the rules of the average dummy load...
But yea, who is worried about any puny amount of tuner loss
when you got 2000 feet of 19 gauge wire loading in the program.. :/
Isn't new science wonderful!

So sayeth Art...

1. As the particles decay over time they are pushed into the surface
of materials by the impact of succeeding arrival of particles up to a
certain depth called ‘skin depth’.

Kind of like stomping grapes to make wine!
This new science can be intoxicating!

==========
Firstly ,it is my understanding that in the USA all terrestrial TV
stations will go digital in 2009 , so it would be useful to know which
are the frequencies/bands this service will be offered in your (Toledo)
area ,before you buy any new antenna.

Secondly ,most ,if not all TV sets nowadays have an antenna input socket
for 75 Ohms coax. Since coax is less 'environment sensitive' than twin
lead feeder , it does make sense to run coax to the antenna.
If the antenna's active element is a folded dipole ,its connection box

will include a (usually pig nose type) 4:1 balun.

If the source resistance of a tuned r-f PA stage was truly non-dissipative, and the tx simply supplied less power into poor matches, how would that explain the catastrophic failures to the output circuit components often seen when high power transmitters operate without suitable SWR protection into highly mismatched loads?

Another reality is that r-f power from two co-sited, tuned transmitters on two frequencies in the same band can be present in each others output stage due to antenna coupling, which causes r-f intermodulation between them. The non-linear (mixing) process occurs at the active PA stage. If reflected (reverse) r-f energy never reaches the PA stage as you assert, then how could this IM generation occur?

RF

I used to live about 10 mi east of Toledo off Ohio Rt2, and my experience was similar to what you are seeing. I was about 4 mi from the Toledo antenna farm; so, anything more than a bent paper clip was overkill for the Toledo channels. Got Detroit, Flint, Cleveland. Never Columbus or Dayon.

After the digital switchover all the Detroit stations will be on UHF. Flint will have 2 UHF plus CH12. Toledo stations will be on 5, 11, 13, 29,, 46, and 49. Cleveland will be all UHF, except for CH8. If you live on the east side, you will be able to get by with a UHF only antenna. Else, I would wait until the CH7 - CH51 antennas get more common. No sense getting a CH3 - 69 antenna because they are 3X as big as a 7 -51 antenna with the same performance. Also, people here claim the big ChannelMaster 8x bow tie UHF antenna works well on the higher VHF channels.

Keep the tower and rotator, but make sure the tower is not rusted out at the base before you let anyone climb it. If you don't want to save the rotator, just point at Detroit and hope.

What I am saying is Thunderbird made it look like you were responding to
my post with a "Works for me!", which you were not.

Moving Thunderbird's settings from:
View->Threads->Unread
to
View->Threads->All
I was able to see you were actually responding to Art's post.

That being said, my response was not out of hand, but I did wonder why
the tone of your post was as such.
Now I understand.

Everyone thanks for the help!

I am looking at the following combination;

Please Chime in with opinions ....

Digicon Coax Cable 50Ft
Winegard HD 8200U High Definition Platinum VHF/UHF/FM Antenna
Channel Master Complete 9521A Complete Antenna Rotator Kit with Infra Red and 100Ft of Rotator Wire
Invisible MultiRoom Frequency Remote Extender (Converts the InfraRed to RF)
I currently have a amplifier- but was looking at a Eagle Aspen 15db (DISTAMP-15GX). I am not really sure if its really needed or not but on my furthest run out to the second Garage it makes a difference there. Probably will skip the amplifier until its needed as mine works fine.

I will get over the height issue of the tower by renting a portable 50ft Lift for around 100 bucks a 24 hr period. I then can clean the tower of the vines, do some trim work on a few trees, and easy place the antenna. The height does not bother me, its the flexibilty of the tower with me on it that makes me nervous. Plus the $100 bucks is far cheaper then falling off the tower. Total bill should be around $450. I was quoted prices in the $800 plus range using my tower when I called around Toledo. Totally new with new tower was $1500-2000. The run of cabling to the house's main antenna connection and power needs (rotator etc) is a breeze as its 12 feet from roof edge to main house panel.

Thanks again,
Chris

Wow, a little dense here. Got you now.

Thunderbird is my favorite newsreader. Thank you for making me aware of what was happening. Now I wonder if this has happened before and taken advantage of my ignorance? Well, at least I have a chance of watching out for this now! Sorry for any misunderstanding on my part.

I just copy-the-mail mostly here; I believe you mentioned you tend to do the same also. New ideas, methods, designs, new construction methods, new ways of looking at old ideas, etc. are what I mainly search for in my personal interests; And, those who share some of their knowledge and use of smith charts, maths, etc. are always of interest to me. Too often threads are just a rehash of some tried-and-true antenna design and construction methods. While this is always of interest to newbies, and should be if not, I tend to skip over them (or, been there, done that, built it, etc.)

However, I was collecting a lot of material on conventional antennas, matching circuits, SWR bridges, etc. and properly indexing it so someone asking a common question or seeking a common design could be referred there without reinventing some ancient conversation describing their constructions, workings, operation, etc.; But, some evil person broke in while I was on holiday and stole a lot of computer equipment here. Among the computer equipment stolen was the USB external hard drive containing the website I was constructing. I have just started the project all over ... A few individuals here have already done this, to some degree and have some material on baluns/ununs, antennas, etc. on a website and available for view.

Warm regards,
JS

You must be talking about solid-state tx when you mention SWR protection. I don't know of any tube tx that have such protection. Any catastrophic failures in tube tx with pi-network output circuits due to poor impedance match at the output without retuning to match the the network to the load simply leaves the tx detuned away from resonance. The result is excessive plate current that would be reduced to normal by resonating the tank circuit. No operator in his right mind would allow the tx to be operated with the tank not tuned for the resonant dip in plate current.

>
> RF
>
:You said two tx operating on two different frequencies, which means the RF signals from the two tx are not phase coherent. In this condition the signal from each tx does enter the other. On the other hand, the wave reflected from a mismatched termination is phase coherent with the source wave, resulting in the addition of the reflected wave to the source wave when either the antenna tuner or the pi-network is adjusted to deliver all available power at the desired grid drive.

> "New Science"...

Don't knock it. I've taken down my HF tribander, 40m beam, 160m inverted L and put up antennas based upon my interpretations of the vast storehouse of technical data posted by Art in the past. Not only are the new antennas much, much smaller, I've been able to contact others in several negative galaxies. ;-)

Wouldn't you love to be a fly on the wall in the Patent Office?

5319. How to calculate wind load area?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-10 20:08:20 UTC
From: Dave99 <dpdphoto@aol.com>
Message-ID: <a424bfb9-7e59-4a4e-b3a1-124fe80dd884@z66g2000hsc.googlegroups.com>
Source record: 25041

Can anyone explain to me how to calculate the wind area for an antenna? I assume you combine the square footage/inches on what would be the largest side, then factor in any round parts... Which if I understand correctly, you do by taking the sum of those round parts and multiply by 2/3? So then you add that with the square parts and that's your wind load area? I'm sure I'm probably missing something.

Thanks,

Dave

Dave, K8MN wrote:
"Wouldn`t you like to be a fly on the wall in the Patent Office?"

My perception of Art`s latest is a dipole composed of elements consisting of 1/4-wavelengths in effect but constructed of helices of 1/2-wavelengths of wire.

My 20th edition of "The ARRL Antenna Book" on page 16-13 says:
"The general approach has been to use a coil made from heavy wire (#14 or larger) with length-to-diameter ratios as high as 21. British experimenters have reported good results with 8-foot overall lengths on the 1.8 and 3.5 MHz bands."

Also, on page 78 of "All About Vertical Antennas" by William Orr, W6SAI and Stu Cowan:
"In general, a half-wavelength of no. 14 formvar-coated wire is spirally wrapped around the form, with turn spacing approximately equal to the wire diameter. This amount of wire will approximate a quarter-wave resonance."

The Unwin Antenna seems to be in Richard Clark`s phrase: "Prior Art".

Best regards, Richard Harrison, KB5WZI

if the load impedance seen at the transmitter terminals is outside the range
that it was designed for you end up with either arcing from excessive
voltage or meltdown from high currents. remember, the pa output as long as
it is connected to a linear load and you consider only the sinusoidal steady
state condition can be completely replaced by a lumped load impedance, hence
no reflections necessary to figure it out... same load, same result, hence
the reflections have no effect on the internals of the pa.

>
> Another reality is that r-f power from two co-sited, tuned transmitters on

> then how could this IM generation occur?

non-coherent input would of course pass through the matching network going
into a pa, there is nothing that precludes that. that current would cause
mixing in the non-linear tube or transistor and therefore im generation.
but that incoming rf is not reflected, it is the incident wave, with nothing
coherent to interfer with why would it not pass into the pa?

Now, have fun with this one... two transmitters on exactly the same
frequency feeding a common load through equal lengths of coax... what

happens if you change the phase relationship between them? make it simpler, remove the coax and connect both pa outputs togther with a single load, now no reflections to worry about... does it matter? do the two pa's feed all their power into each other? where do the reflections go??

U R kidding, right? Or, are you just attempting to play the part of a
LARGE idiot?

If USENET is dropped by major ISP's, as already has began (actually
forced the the Attorney General), there will be no antenna newsgroup
left. I don't know how that could be more fitting to be discussed here!

Please tell me you were just blind, and not that big an idiot--from past
discussions here I am beginning to believe this NG is full of such ...
it causes one to doubt the sanity of many here.

"If the source resistance of a tuned r-f PA stage was truly non-dissipative, and the tx simply supplied less power into poor matches, how would that explain the catastropic failures to the output circuit components often seen when high power transmitters operate without suitable SWR protection into highly mismatched loads?"

The PA is a switch. Almost no voltage across it when it is closed and no current through it when it is open. Some of its impedance is dissipative and some is non-dissipative.

A conjugate match to its total impedance is the way to deliver maximum power from the transmitter to its load. Alexander H. Wing wrote on page 43 of "Thansmission Lines, Antennas, and Wave Guides":
"If a dissipationless network is insrted between a constant voltage generator of internal impedance Zg1 and a load ZR such that maximum power is delivered to the load, at every pair of terminals the impedances looking in opposite directions are conjugates of each other."

An operating transmitter is normally adjusted for conjugate match with its load.

Normal plate dissipation occurs when electrons strike the anode and there is little damage to the tube when the current and cooling are within limits.

Let an arc strike across the transmission line and it may effectively become a short circuit which may impose an enormous mismatch in an instant to the transmitter. That`s why a d-c supply is often connected in series with a relay coil across the transmission line. The arc completes the d-c circuit energizing the relay which breaks the interlock circuit. The transmitter instantly is shut down until it is manually restarted.

Tubes are often destroyed by internal arcs if overloads don`t act in time.

Best regards, Richard Harrison, KB5WZI

To the best of my knowledge the Attorney General hasn't taken a
stand about/against the average newsgroup, only those such as the
child porn groups. If that isn't so, please enlighten me. Adult porn
groups, dealing with those above the age of consent, haven't been
banned as yet, probably won't be. I can see a difference there, can
you?
I can't see that your 'free speach' has much to do with antennas
either...

Dave,
That's probably as accurate as needed. Probably the average person just figures the 'square' area and leaves it at that. At least that would give you some 'wiggle room' when figuring what support is needed. If you're talking about graded classroom stuff, you're on your own! Been too long for me...

> circuit components often seen when high power transmitters operate
> without suitable SWR protection into highly mismatched loads?

the output network might be non-dissipative, but that doesn't mean that the voltages and/or currents won't exceed the limitations of the components.

Consider a gedanken.. you have an active device acting as a shunt DC regulator that puts out 1 amp at 1000 volts into a matching network, the other side of which is a 50 ohm load. The power supply is a 5000 volt power supply with a 2000 ohm dropping resistor, and 1 amp is also flowing through the active device. The 2 amps total flowing through the dropping resistor results in the 1000 volt output into the network. The implication is that the matching network, with the 50 ohm output, is presenting a 1000 ohm load.

Now, say you change the load impedance on the network so that the impedance on the input side is zero ohms. Now, the voltage across the active device is zero volts, the voltage across that dropping resistor is 5000 volts, instead of 4000 volts, and it will get a bit hotter, and possibly fail.

Or, say you change the load impedance so that the input of the network presents an infinite impedance. The same 1 amp is flowing through the active device (say it's a controlled current source), but, since there's no load current, the voltage drop across the resistor is now 2000 volts instead of 4000 volts, and the voltage across the active device is now 3000 volts instead of 1000. If the device can only take 2000 volts,

it's cooked.

Actually, I am for less govt. involvement, NOT more.

However, child porn perverts and their groups is/are one large exception and the govt. banning them would be greatly appreciated by the vast majority.

I think it is obvious some people do not read the material before they begin to enter into the discussion (such as the URL of the article I gave when this thread began.) And, actually, this is good. It gives us warning that we need not be bothered giving them and they their text any consideration(s) at all, i.e. those arguing solely for the purpose of argument--and then only responding with arguments contrary to "common logic." (akin to common sense)

Perhaps they want USENET and r.r.a.a. gone! Who knows what logic drives them--indeed, one can easily draw the conclusion that no logic whatsoever is involved in their text.

The rest of us should write our public servants and demand they take action against this rogue Attorney General, his actions are truly un-American. The ISP's should also be written and/or any subscriptions to their services be dropped.

However, with the number of politicians caught engaging in perversions and/or inappropriate sexual behavior, perhaps only the child porn groups will be left on USENET--and those only populated by our public servants--on their private ISP supported by public monies!

Ya never know, ya just never know ... :-(

The most accurate way is to measure Zo as directly as you can.

Most of these lines have an actual Zo somewhat different to their nominal
Zo.

For most constructions where the conductors are mainly surrounded by air,
you can get a close idea by treating them as an air spaced line.

The calculator at http://www.vk1od.net/tl/twllc.htm allows you to supply
the conductor diameter and spacing, and it will calculate Zo (and a lot
more). If you fiddle with the value of relative permittivity to change the
velocity factor (if you know it), you will get a better approximation.

The OP's question related to Class B and Class C.

Have you hopped on another tram?

Your statement is definitely not true for Class B RF PAs. In fact it is difficult achieving theoretical Class B efficiency with tetrodes running on relatively low HT (eg 750V as in many transceivers).

If what you state was true, you would expect conversion efficiencies in excess of 95%... and that just doesn't happen with practical electron devices.

Practical Class C electron devices cannot achieve those efficiencies at maximum continuous output power. The anode voltage waveform in practical continuous Class C amplifiers with resonant loads is hardly the rectangular pulse waveform that you suggest. In fact, if you observed it with a CRO you would be hard put to argue that it wasn't an almost pure sine wave.

There is no need to become emotional, "John". Perhaps your mind has been
slightly compromised by one too many injestions of lysergic acid
diethylamide in your earlier years. Take a deep breath and tell yourself
"People in rraa really like me. I am a good person. I am smart. People know
that. And people really do laugh at the absurd nonsense that I write
sometimes, even if I'm not quite sure 'why' I write it myself."

> over ...

Now what makes you believe it is a 'good thing' to focus on one's self?
Surely you can see what happened to Art after he tried that and ended up
with the MI5 postings. He then refocused into the academic realm and ended
up designing neutrino antennas. His recovery has apparently not been quite
as successful as your's. Sorry "John" but I think people should pass on your
advice, even if it is free.

1) Those are not antenna groups.

2) If USENET is made inaccessible, those groups will be gone also.

3) You did NOT read that article, else you are unable or unwilling to realize USENET is very much in danger. There is/was no reason to force those ISP's into dropping USENET support, dropping the perv groups would be enough. Once USENET is gone it will be too late to become aware of what is happening ... now this has been explained enough, if you can't get it by now--you won't ever ...

Trust me, if you don't have the resources to realize the importance of the actions being discussed (and, you can read the comments on the URL I originally gave to see others concerns) just relax, others can move to protect your rights for you ...

Antennas are not electromagnetic devices?

Antennas are not amateur radio equipment?

Antennas are not homebrewed by hams?

Antennas are not a suitable subject for discussion among hams?

> 2) If USENET is made inaccessible, those groups will be gone also.

All American ISP's could drop their USENET feeds and it would not
make USNET inaccessible.

A bunch of clueless dillhole web users would lose access, but that would
be for the better of all.

You obviously haven't a clue what USENET is or how it works.

Give twinlead a twist every couple of feet and you save the cost of that
coax.
At the freqs used, most coax could be rather lossy, depending on the length
of the run, but twinlead has a very happy combination of being low-loss -
and - low-cost compared to most coax. (And lighter weight too.)
The 4-1 balun (coax to twinlead adapter) is cheap enough.
I've used twinlead and tv baluns for a 200-ft run to my antenna on 10 meters
(5 watts) with good results both tx and rec.
Ya just gotta match impedences and you're good to go.

When it's new, when it's clean, and when it's dry.

As I understand it, one of the bigger downfalls of ordinary 300-ohm
twinlead for TV reception is that its performance can deteriorate
rather badly with age. Sunlight causes the PVC to deteriorate, and
surface contamination and moisture (e.g. rain) can significantly
increase the losses.

Coax is much less vulnerable to these problems.

It's also subject to problems if it is too close to things, remember those special standoff insulators for it? It can not be looped, wrapped around things, etc.

Geoff.

But several national ISPs (cable-based privders, generally) are taking
the easy way out by dropping their internal USENET service entirely.

The independent commercial and free servers will still be around (for
a while, anyway).

I fail to understand how the limitations of the components have anything to do
with the output resistanceof the network. Can you please explain how this is
relevant?

Sorry Jim, I'm not familiar with a 'gedanken'. Is it distant cousin of a Class B or C amplifier? Your discussion above doesn't appear to have any relation whatsoever to those types of RF amplifiers. Are you using your discussion in an attempt to prove that the output resistance of those types of amps is not non-dissipative? Or what are you trying to prove? I don't get it.

Owen Duffy wrote:
"Have you hopped on another tram?"

Maybe. I agree. Radio power amplifiers have clean sinusoidal outputs, otherwise they would generate unacceptable harmonics. All except Class A amplifiers which have continuous plate current flows and a maximum efficiency of 50%, have plate currents which flow in pulses.

In Class B, the plate current in individual tubes flows in pulses of approximately a half cycle. Actual efficiency is about 60%.

In Class C, the plate current pulses last less than a half cycle. Practical efficiencies are in the range of 60 to 80 per cent.

Best regards, Richard Harrison, KB5WZI

All,
I think the antenna has a coax connection built into it (One of
advertisements I saw). Also the previous wire was coax as is the rest
of the house. So I think Coax is a given for me due to simplicity and
never having any problems with it in the past. I will keep it in mind
though if something would change on the antenna or plans.

Thanks again,
Chris

Something tells me there is a common thread which runs though most of
his problems--a solution to that thread will end most of of the problems
he complains of with a single action.

The one you suggest could just be just such a solution. :-)

I was attempting to discuss the comment above:
"how would that explain the catastrophic failures to the output
circuit components often seen when high power transmitters operate
without suitable SWR protection into highly mismatched loads?"

"gedanken" refers to an intellectual exercise describing an experiment
with (usually) contrived or idealized circumstances so that the
underlying concepts can be understood. Classics are Schroedinger's cat,
Maxwell's demon, etc.

http://en.wikipedia.org/wiki/Thought_experiment for more details and
history than anyone could want.

> without suitable SWR protection into highly mismatched loads?

This question has been asked many times (several times by you, as I recall) and answered (several times at least by me) on this forum. The answer is that when a transmitter is terminated in an impedance too far from the one it's designed to see, voltages and/or currents in the transmitter and tank circuit rise to unacceptably high values. This causes the damage or destruction.

I don't think this is difficult to understand. So the reason for the need to keep asking is that it's apparently not being believed, presumably because of the deeply compelling need to see waves of "reflected power" entering the transmitter to wreak havoc. But the simple answer is true. This is very much like trying to convince an astrology believer that he stubbed his toe because he didn't watch where he was going rather than because Mars was lined up with Jupiter.

> Another reality is that r-f power from two co-sited, tuned transmitters

> If reflected (reverse) r-f energy never reaches the PA stage as you
> assert, then how could this IM generation occur?

Power from one antenna is coupled to the other antenna by a process known as "mutual coupling". This power enters the other transmitter via normal transmission along the transmission line, where it reaches the final stage for mixing. No mysterious "reverse r-f energy" is needed to explain this well-known and well-understood phenomenon.

Bravo! Endless self-indulgent mental masturbation appears to be the function of far too many posts over the last several years. This has virtually ruined what at one time was a fine resource for amateurs interested in antennas. I used to recommend that people who had questions about or interest in antennas come to this newsgroup. I stopped doing it, and now only take a look myself every week or two to see if anything has changed...it only seems to get worse.

It's a damn shame what a few frequent posters have done to this newsgroup.

What's more irritating is that people respond to it. I plonked "John Smith" quite some time ago, so I'm not bothered at all by his rantings, since I don't even see them. But I do see the responses from the folks who respond to them. The best way to deal with this kind of posting is to ignore them. Ignored OT posters go elsewhere, where they can get the attention they're after, before very long. But they don't if they get a constant supply of it.

I guess that all implies that if ISPs drop USENET it just doesn't matter, this will not set a trend, the attorney general will just stop with the few he has already manipulated, this will not set the stage encourage frivolous lawsuits--I can't help but differ with that ...

Perhaps they wish to imply that only dimwits use the ISPs in question (the ones which have discontinued USENET)... I simply have no way to prove/disprove that ... however, I suspect NOT!

Perhaps it implies government manipulation of the channels of citizens communications is a good thing ... I think not.

Perhaps it implies that ISPs dropping USENET (and this NG) is a good thing which just falsely appears to be an evil ... again, I differ ...

Perhaps the people who use the pervert NGs are the ones screaming not to worry? They might fear this will focus attention on their perversions? Hmmm ... I wonder, however, sometimes I am given to bouts of paranoia.

Perhaps I am the problem; just plonk me and ISPs dropping USENET are seen for what they really are--only a figment of my imagination. Plonk me and you will immediately realize it is all just a phony bad dream ... well maybe, who knows.

But, I think it all points to the logic of a few which attempts to drive the direction of this newsgroup. A few remain blind to the insanity they drown in ... :-(

I leave this to others to sort out. However, if the small group of illogical amateurs which have manipulated amateur radio are able to influence the course of the internet, why would we think they would do any different than they have done with the amateur bands? i.e. stagnation, decay, good-ole-boys-club mentality, loss of importance, ancient equipment designs, resistance to progress, etc.

But the offending impedance equals (Vfor+Vref)/(Ifor+Iref), a
virtual impedance caused by the superposition of the reflected
wave and the forward wave.

> I don't think this is difficult to understand.

What is difficult to understand is the denial of the role that
the energy content of the reflected wave plays in causing the
offending impedance. If it were not for the reflected waves,
that offending impedance would never happen.

Pulses is not very descriptive, it is definititely not rectangular
pulses as implied by your earlier posting.

For a single ended RF common cathode valve PA with resonant load, an
active device that is perfectly linear and zero saturation voltage,
theoretical efficiency is 79% in Class B.

If saturation is only 20% of the supply voltage, that figure drops to
63%.

For HV tubes, saturation of about 10% of the supply voltage is
reasonable, and efficiency is that case is 71%.

Then the output circuit loss need to be factored in, and 90% is not an
unreasonable output circuit efficiency.

The comination of 10% saturation and practical output circuit arrives at
64% efficiency overall (ie plate and output circuit) ... but tetrodes on
low voltage can't usually deliver low saturation voltage and won't reach
that figure.

>
> In Class C, the plate current pulses last less than a half cycle.
> Practical efficiencies are in the range of 60 to 80 per cent.

Again, not rectangular pulses, not nearly.

For most practical valves in continous mode, they cannot develop their
rated maximum power at very small conduction angles without exceeding
rated cathode current, so there is often little benefit in operating at
conduction angle much below 120 degrees.

Practical efficiencies are in the range of 60 to 80 per cent."

Owen Duffy wrote:
"Again, not rectangular pulses, not nearly."

A pulse does not need to be rectangular. According to my electronics dictionary:
"Pulse - 1. The variation of a quantity having a normally constant value. This variation is characterized by a rise and decay of finite duration. 2. An abrupt change in voltage, either positive or negative, which conveys information to a circuit. (See also Impulse.)"

A rectified sine wave could properly be called a string of pulses being constantly off between pulses then rising and falling between pulses for a short finite duration.

Recall that valve/tube diodes in rectifier service were not used with capacitive filters because the rated peak to average current ratio was something like 1.5:1. Modern, solid-state diodes can have ratios of 40:1 and can be happy with capacitive filters in rectifier service.

Peak current limits of high-voltage, high-power tubes is a real physical limit. The cathode can only emit so much.

Cecil, W5DXP wrote:
"What is the linear source impedance of a class-C amp?"

A conjugate match is necessary for maximum power transfer.

A Class C amplifier is not inherently linear. That is disasterous for an already modulated AM signal but it is of no importance to an FM signal. As Richard Fry points out, no tank circuit is required. A low-pass filter to suppress all harmonics is all that is needed for a clean signal. No tuning is required of a tank at the operating frequency.

A tank circuit is not selective enough to prevent intermod anyway. When I worked the morning shift at 790 KHz in Houston, and I fired up the transmitter, I would hear 740 KHz`audio coming out of the monitor speaker. They started programming earlier than we did. They were 15 miles away. Our transmitting antenna made a dandy receiving antenna. The received 740 KHz modulated our final amplifier and we rebroadcast it although at a level much lower than our own modulation. Any one listening to 790 KHz who turned up the volume to hear the 740 KHz audio got their ears knocked off when our modulation started. We had high level plate modulation of the final amplifier for our own signal. For the 740 KHz signal the level of modulation was much lower, millivolts not kilovolts. Either program was cleanly modulated on our carrier. The only difference was the enormous difference in modulation levels.

Best regards, Richard Harrison, KB5WZI

In this part of the world, connection of an overall leading PF load
usually requires approval of the supply authority. Most electricians
would be aware of the restriction.

The reason being is that it can cause an increase in supply voltage
beyond spec in the local area.

Yes, large factories for example may use static or rotary power factor
correction to improve their PF for tariff reaons, but if an installation
reaches an overall leading PF it usually breaches rules in this part of
the world, and commonly permission is required to attach individual
'devices' with capability for leading PF. Some tariffs are based on
maximum demand, and often maximum apparent power (ie VA), not maxiumum
real power (ie W), hence the economic interest in PF correction.

Today, active static power factor correction that can dynamically track
a varying load at varying PF is a lot more attractive than rotating
machines.

Yes Richard, pulse can mean all things to all people... but you did say "The PA is a switch. Almost no voltage across it when it is closed and no current through it when it is open." That implies a rectangular current pulse... and I think we are now agree that is not the case for Class B or Class C (which were the stated scope of the OP's question).

The quote above reads as though the existence of reverse (reflected)
r-f energy is being denied.

For skeptics, the link below leads to a field report showing a measurement
of the reflection of a narrowband r-f pulse by an analog broadcast TV
antenna, back toward the source. The H.A.D. of the sinï¿½ pulse used
represents the shortest transition time that can be accommodated in a ~ 4
MHz transmission channel.

Note that the reflected pulse appears some 6.2 ï¿½s after the incident pulse,
which corresponds to a round trip through the ~1,525 feet of 6" OD, 75 ohm,
air pressurized transmission line leading to the antenna in this system.

The return pulse amplitude indicates a far-end match (elbow complex +
antenna) of about 1.05 VSWR (2.3% reflection).

Especially strange since the "reverse r-f energy"
is the cause of the impedance responsible for the
mismatch problem. If there were no "reverse r-f energy",
the impedance causing the mismatch wouldn't even exist.
Why is the cause of the offending impedance of no importance?

Richard, its a common myth that Class C amps are non-linear, but the truth of the matter is that although the condition at the input of the pi-network is decidedly non-linear, the energy storage in the pi-network tank circuit isolates the input from the output and the result is a totally linear condition at the output of the pi-network. Evidence proving this is true is that the output of an unmodulated signal at the output of the network is an almost pure sine wave. With a Q of at least 12 the difference between a pure sine wave from a signal generator and that from the pi-network output can not be seen on a dual trace scope with the traces overlapping.

I don't know about the energy storage in the filters you mention, but I would assume that if the filter output is a sine wave then the energy storage required to produce a linear output is sufficient.

Cecil, W5DXP wrote:
"Is the class-C amp conjugately matched during the 75% of the cycle it is off?"

We must consider the complete cycle.

Working with spark ignition systems (Hettering) you may have encountered a "dwell meter". It indicates the % of the time ignition points are closed. When the points are closed, impedance between the meter and the battery is insignificant. The meter if left continuously connected through the points would indicate full-scale. When the points open, their impedance is infinite. Left continuously open, the meter indicates zero on the dwell scale.

Dwell is measured while the engine is rotating and the meter is being connected intermittently to the battery through the ignition points.

Intermittent opening and closing of the points causes the same scale reading that would be caused by replacing the points with some particular value of fixed resistance (a resistor).
The main difference is that no dissipation occurs in the open ignition points and precious little energy is lost in the closed points. Voila! We have produced a dissipationless resistance.
The Class C amplifier is a switch which operates in the same manner. The Kettering ignition points have a low-resistance ignition coil primary in series, and the Class-C amplifier has a tuned plate circuit in series, but both are being switched on and off repeatedly.

Best regards, Richard Harrison, KB5WZI

Walt, W2DU wrote:
"I don`t know about the energy storage in the filter you mention, but I would assume that if the filter output is a sine wave then the energy storage required to produce a linear output is sufficient."

As a former FCC official, Walt knows their regulations sharply limit harmonic content of FM broadcast carrier frequencies. A sine wave must be pure, otherwise it has harmonic content (not allowed).

Matched across what boundary? from output pi network to load?
From active device to pi network?
I'd venture that between active device and pi network, there isn't a conjugate match, at any given instant, and perhaps not even considered over the entire cycle (without resorting to some things like "apparent impedance" which doesn't have a real clean definition).

In order to provide a true "conjugate match" to a device that is changing state, the load must also be changing state: i.e. the match is single valued, for any Zload, there is a single Zmatch that maximizes power transfer; except perhaps for some trivial cases, like Z=zero or infinity, but in such cases, the load doesn't dissipate ANY power, so what is there to maximize.

Furthermore, if one looks at situations where you have, for instance, a very low source impedance (a stiff voltage bus) or a very high source impedance (a constant current source), power transfer is maximized to a given load impedance when the reactive components are conjugate. In such a case, the source and load resistances are not equal.

One might look at
http://p1k.arrl.org/~ehare/temp/conjugate_match/conjugate_match_theorum.pdf
http://mysite.orange.co.uk/g3uur/index.html

I would say "apparent resistance".. the "conjugate match" and any other linear circuit analysis can't necessarily be "averaged". Something like Kirchoff's current law or voltage law (or Ohm's law, for that matter) has to be true at any instant.

The challenge faced by folks faced with analyzing "real" circuits is that you have to be careful about how you turn a circuit that is likely time-varying AND nonlinear into a linearized approximation. For instance programs like SPICE's transient analysis uses linear circuit theory (via matrix analysis) in combination with an iterative differential equation solver, and tries to treat the circuit as linear at a given instant. (granted, newer versions of SPICE and its ilk are a bit more sophisticated, since they can handle nonlinear terms in the matrix).

> Kettering ignition points have a low-resistance ignition coil primary in
> series, and the Class-C amplifier has a tuned plate circuit in series,
> but both are being switched on and off repeatedly.

Complicated substantially by the fact that the active device in a RF amplifier generally doesn't act as an ideal switch. So the piecewise linearization you describe isn't totally applicable. For instance, a BJT acts like a constant current source if base drive is fixed, but in RF circuits, the base drive isn't fixed. In FET circuits you worry about the gate capacitance.

This is why there are all sorts of variants of SPICE modified for switching power supplies.

I'm not trying to be difficult, but I just resurrected the
Fourier equation for the output of a class-B amplifier. It is:

i = 0.318Im + 0.500Im*sin(A) - 0.212Im*cos(2A) - 0.0424Im*cos(4A) - ...

The second harmonic is 42% of the amplitude of the
fundamental frequency at the plate of the tube amp.

OK Cecil, if the 2nd harmonic is 42% of the amplitude of the fundamental at the plate of the tube, can you determine the amplitude of the 2nd harmonic at the output of a pi-network having a Q of 12?

I think I understand ideal class-A operation pretty well.

What I am trying to understand is: In class-B operation,
if the frequency of interest is made up of less than 1/2
of the current through the amplifier tube, is more than
1/2 of the current not conjugately matched?

Quoting w2du's web page:
ï¿½The Conjugate Theorem also shows that in a sequence of
matching networks it is necessary to match at only one
junction *if the networks are non-dissipative*. In actual
practice, since there is usually some dissipation, it
is frequently desirable to adjust at more than one point.ï¿½

True is true no matter what anyone says. I`ve never seen Terman misspeak.

On page 255 of his 1955 opus Terman wrote:
"---the Class C amplifier is adjusted so the plate current flows in pulses that last less than half a cycle."

On page 450 he wrote:
"The high efficiency of the Class C amplifier is a result of the fact that plate current is not allowed to flow except when the instantaneous voltage drop across the tube is low; i.e. Eb supplies energy to the amplifier only when he largest portion of the energy will be absorbed by the tuned circuit."

Sounds like a switch to me. When switched on, voltage drop across the tube is low. When switched off, voltage drop across the tube is Eb, but since current is zero, no power is lost at that instant in the tube.

Richard, try this: Let Google translate it from PDF to
HTML for you.

Do a Google search for "w2du reflections
chapter 19A".

One of the first entries will be a hit
at http://w2du.com/r3ch19a.pdf .

Under the Google entry for this, carefully look for
the words:
"File Format: PDF/Adobe Acrobat - View as HTML"

The words 'View as HTML' will be linked to Google's
HTML translation of the PDF.

The translation isn't pretty, but the essentials are
there. You will have to fill in some of the blanks
yourself.

Posting this as well for anyone else experiencing this
problem.

Jim, K7JEB

Lets plug some real world numbers in...

Take a DC supply of 1000V, and a valve that saturates at 200V, the RF approximately sinusoidal voltage swing on the anode is from 200V to 1800V. (For avoidance of doubt, whilst the RF voltage on the anode is approximately sinusoidal, the anode current waveform is not.)

If the conduction angle is 120 degrees (typical for Class C amplifiers), the valve starts conducting at about 1000-800*sin((180-120)/2) or 600V instantaneous anode voltage... and continues conducting as the instantaneous anode voltage passes through the minimum and rises again, cutting off when then instantaneous anode voltage again reaches 600V. In this case, the anode voltage during conduction varies between 400 and 600V, 40% to 60% of the supply voltage.

The switch analogy is not a good one.

>When switched off, voltage drop across the tube is Eb, ...

That is wrong. The anode voltage is approximately a sinusoidal voltage swing of almost (70% to 90%) Eb zero to peak superimposed on the DC supply voltage (Eb).

You have taken a quote from Terman and weaved your own flawed extensions (being the switch analogy and the statement about instantaneous anode voltage).

Owen

I wrote:
"When switched-off, voltage drop across the tube is Eb"

Owen Duffy wrote:
"That is wrong."

Yes as a general statement, that is wrong. The instantaneous drop across the tube is the sum of Eb and EL, the signal voltage across the load.

Terman shows this in Fig. 13-1(b) on page 449 of his 1955 opus.

Fig. 13-1(e) shows the plate current pulse which is less than 180 degrees in duration as the tube is biased beyond cut-off.

My switch analogy is imperfect but good enough to exemplify dissipationless resistance as a part of the output impedance of a Class C amplifier.

Well, there are mechanical switches, digital switches,
and analog switches. I suspect a class-C amp falls
under the heading of an analog switch.

Hi Walt,

R is by definition a physical "property of conductors which depends on dimensions, material, and temperature". So if we multiply both sides of our "ratio" equation by I^2 to convert to power we get V*I = I^2*R. Given that V, I, and R are all non-zero, why would you ask us to believe that I^2*R and V*I could be zero? It's true that V^2/R is a ratio. And I guess it's probably also true that the equation itself doesn't dissipate power. But what would you have us believe that that is supposed to prove?

That is a new / unconventional definition of 'linear'.

The term is usually used in this context to mean a linear transfer characteristic, ie PowerOut vs PowerIn is linear.

Considering a typical valve Class C RF amplifier with a resonant load:

Conduction angle will typically be around 120°, and to achieve that, the grid bias would be around twice the cutoff voltage.

If you attempted to pass a signal such as SSB though a Class C amplifier that was biased to twice the cutoff value, there would be no output signal when the peak input was less than about 50% max drive voltage, or about 25% power, and for greater drive voltage there would be output. How could such a transfer characteristic be argued to be linear?

Owen

I always believed that a ratio was a comparative measure between like units - e.g. forward voltage to reverse voltage, output power to input power etc. Voltage to current is not a ratio. V/I has dimensions of resistance - ratios are dimensionless.
Alan

That's only one definition. From "The IEEE Dictionary",
the above is definition (A). Definition (B) is simply
"the real part of impedance" with the following Note:
"Definitions (A) and (B) are not equivalent but are
supplementary. In any case where confusion may arise,
specify definition being used."

Definition (B) covers Walt's non-dissipative resistance.
A common example is the characteristic impedance of
transmission line. In an ideal matched system V^2/Z0, I^2*Z0,
or V*I is the power being transferred under non-dissipative
conditions.

I have made many measurements
> that prove this.

Hi Walt,

R is by definition a physical "property of conductors which depends on
dimensions, material, and temperature". So if we multiply both sides
of our "ratio" equation by I^2 to convert to power we get V*I =
I^2*R. Given that V, I, and R are all non-zero, why would you ask us
to believe that I^2*R and V*I could be zero? It's true that V^2/R is
a ratio. And I guess it's probably also true that the equation itself
doesn't dissipate power. But what would you have us believe that that
is supposed to prove?

73, Jim AC6XG

Hello Jim,

I don't understand how my statement in the email above indicates that I^2*R and
V*R could be zero. The simple ratio of E/I is not zero, yet it defines a
resistance that is non-dissipative because a ratio cannot dissipate power.

Walt

"The IEEE Dictionary" is careful to differentiate between
an E/I ratio equaling an impedance vs an "impedor" consisting
of physical components.

Hi Walt -

If E and I are not zero, then E*I is not zero. But you are correct
that the equations themselves do not dissipate power. :-) Resistors
do, however. If there isn't an actual resistor located where you make
your measurement, then of course there's no power being dissipated
there.

Yes, until we name them. Cycles / seconds is now called Hertz.

My electronics dictionary defines ratio -
"The value obtained by dividing one number by another."

Simple and no qualifications.

From Newton:
Acceleration = force / mass

You must pick the right units or use constants to make the numbers work.

Some people are persuaded that resistance = loss. Not so at all. Resistance is just a name given to the ratio of voltage to current. A perfect reactance produces a voltage drop but no power is lost. A transmission line can be lossless enough to qualify and have a Zo = sq rt of L/C. Reg Edwards used to say that if your perfect line were long enough you could measure its Zo with an ohmmeter. Reg was right because no reflection would ever return to change the current supplied by the ohmmeter.

Free-space has a lossless Zo of 120 pi (or 377 ohms) according to page 326 of Saveskie`s "Radio Propagation Handbook". This is a ratio which is related to volts and amps but is actually the ratio of the electric field strength to the magnetic field strength in an EM wave. The volts and amps are in phase so it has the units of a pure resistance.

Best regards, Richard Harrison, KB5WZI

Owen, 'linear transfer characteristic' isn't the only context for the use of the word 'linear'. Even though the input circuit of a Class C amplifier is non-linear, the output is linear due to the energy storage of the tank circuit that isolates the input from the output, therefore, the output is linear. Proof of this is that the output signal is a sine wave. In addition, the voltage and current at the output terminals of the pi-network are in phase. Furthermore, the ratio E/I = R appearing at the network output indicates that the output source resistance R is non-dissipative, because a ratio cannot dissipate power. This resistance R is not a resistor.

Jim, have you reviewed the new section Chapter 19A that appears on Cecil's website that he uploaded on June 7? It appears there posted as 'Chapter 19A from Reflections 3'. If you haven't reviewed it I urge you to do so, especially the last portion where I report the measurements I made with a complex impedance loading the amplifier. These measurements prove two things: 1) that the output resistance of the amp is non-dissipative, and 2) that no reflected energy reaches the amp tube, and in fact the measurements show that the tube doesn't even see the reflected power. When you see the numbers and understand the procedure I used in obtaining them you will be hard pressed to disagree with the results.

The ratio of width to height of typical computer displays
A ratio is a quantity that denotes the proportional[citation needed] amount or magnitude of one quantity relative to another.

Ratios are unitless when they relate quantities of the same dimension. When the two quantities being compared are of different types, the units are the first quantity "per" unit of the second - for example, a speed or velocity can be expressed in "miles per hour". If the second unit is a measure of time, we call this type of ratio a rate.

Fractions and percentages are both specific applications of ratios. Fractions relate the part (the numerator) to the whole (the denominator) while percentages indicate parts per 100.

Note, Alan, the expression "When the two quantities being compared are different types......

Hi All,

It has taken considerable restraint not to ask some pointed questions:

1. Is a metal wire wound resistor NOT a resistance because it is not
carbon?

2. Is a carbon resistor NOT a resistance because it is not metal
wire-wound?

3. Is a Tube NOT a resistance because it contains no metal?

4. Is a Tube NOT a resistance because it contains no carbon?

5. Is a cathode resistor NOT a resistance when the tube conduction is
zero?

6. Is that same cathode resistor NOT a resistance because it conducts
non-linearly for some speciously constrained (and myopically chosen)
incomplete cycle of time?

finally, and possibly the only compelling logic that seems to flow
from this thread:

7. Is a Tube NOT a resistance simply because it lacks the familiar
shape of an axial lead resistor? (Or, rather, that a familiar axial
lead resistor cannot be found soldered between cathode and plate
within the vacuum?)

I have offered a spectrum of questions guaranteed to be accessible to the buffet style of responding to cosmetic issues instead of substance.

As this is all Rhetoric, I will take the author's prerogative to short-cut the anticipated sputterings of denial, condemnation, damnation, and outrage.

1. 2. 3. and 4. Carbon is a metal.

3. and 4. Plate dissipation bears scant relation to Ohmic Loss. And yet there is heat there that is correlatably and causally related to match, loss, and drive - from any "source."

4. there are many power tubes with Graphite (carbon) plates. The original 813B comes to mind. Some power tubes have their screen grids graphite (carbon) coated too! (Ohm's law still does not appreciably account for plate dissipation.)

5. and 6. are sucker bait for those who would prove the world is non-linear because of the discontinuity at the time of the big-bang (or creation, take your pick).

7. Is, as I intimated, the implicit populist choice (masked as a question) for those who cannot say what the source resistance IS, but are over fulsome by half to say what it is NOT.

Describing what source resistance is NOT is like moving the stacks of brass disks between the Towers of Hanoi. You can do that forever without really coming to any conclusion. Given the length of many threads that imitate this behavior, its popularity marks its less than stupendous insights. But lest I interrupt the modern interpretation of that game as it is played here, I would point out that parsing "ratio" is even more funny. It sure beats Brett dragging the cesspool for newspaper reports of cures for cancer.

Hi Walt,

A few issues....

Yes, I understand the context in which you mean linear (though I have issues with your proposition)... but my comment was referring to the assertion that 'no harmonics' relates to linear operation which seems to me to refer to the transfer characteristic linearity context.

I do have issue with your stated 'proof'. Firstly, I must qualify that we are talking steady state... the mention of resonant loads means we are in the frequency domain. Whilst it might seem that the tank circuit / pi coupler / whatever is just a network of passive parts and they are all linear, the energy that is supplied to that circuit in each cycle depends on the resonant load impedance and traditional PA design methods suggest that that Eout/Iout relationship is not linear for changes in load Z, although it might be approximately linear over a small range.

I recognise a distinction between resistance (the ratio of E/I) and a resistor (one type of component that exhibits resistance)... but I would not claim that resistance is just a 'ratio' because it implies it is a dimensionless ratio.

Owen

Well, someone has redefined "ratio" since I went to school. My old maths
text book says "The term ratio is used when we wish to compare the size
ofr magnitude of two quantities (or numbers) of the same kind, i.e.,
expressed in the same units, and is measured by a fraction"
All my dictionaries say much the same thing. There is no mention of
comparing quantities of different units. That to me would be like
comparing apples with oranges.

Alan

Dear Dave (no call):

If you wish to get down to details, the standard for most of such calculations can be found in ANSI/TIA standard 222G. Put 222G and wind - or the like - into Google. A copy of the standard itself is expensive. Earlier versions were quite inexpensive.

For low towers and antennas, especially in an urban or built-up area, simple is usually good enough.

If you define resistance as simply V/I with no regard to phase, then what you say is true but if V and I aren't in phase then you have impedance consisting of real and imaginary components - resistance AND reactance.

I suppose you could also say that a real resistor is also lossless as the heat due to I*I*R is radiated into space and thus is not lost :)

I found a note I intended to post but don`t see it so I suppose it was lost in cyberspace somewhere. I was responding to Owen Duffy.

Owen wrote:
"How could such a transfer characteristic be argued to be linear?"

I responded:
Conditioning.

Class C amplifiers are used lawfully in great abundance. That is proof enough that they are relatively free from distortion. Pulses in plate current don`t prevent the output of the Class C amplifier from becoming a pure sinusoid. Just as an internal combustion engine uses an almost endless string of exlosions in its cylinders to produce a smooth uniform rotation of its crankshaft and flywheel, the Class C amplifier uses an almost endless series of pulses to produce a smooth sinusoid.

I will quote B. Whitfield Griffith, Jr., Principal Engineer (retired) at Continental Electronics, Dallas Texas, builder of many of the world`s most powerful radio transmitters. Griffith says on page 500 of "Radio-Electronic Transmission Fundamentals", that it is important where you couple the load to the Class C amplifier:
"Figure 56-2 shows how the class C amplifier might look in a typical arrangement. Many refinements of the circuit, which are necessary for practical reasons, are omitted here, since we are concerned only with the fundamental principles of its operation at this time. The plate load impedance consists of a tank circuit of a type similar ro that of Fig. 15-5; the difference is that the load resistor is in series with the inductance rather than the capacitance. This is the preferred arrangement, because the harmonic components of the plate current all have frequencies higher than the fundamental and quite naturally tend to follow the capacitive branch of the circuit. By extracting power from the inductive branch, therefore we can expect to find less harmonic energy in the output than would be present if we loaded the capacitive branch. This load resistance may be an actual resistor, if we wish to feed the output of this amplifier into a dummy load for measurement purposes, or it may be the input resistance presented by some type of impedance-matching network so arranged that the loading of the amplifier can readily be varied. Another common method is to couple resistance effectively into the tank inductance by means of the mutual inductance between the tank and a secondary coil which is coupled to it magnetically, where resistive loads appear in the secondary circuit.

There is also shown in Fig. 56-2 the r-f waveform of voltage and current which we would expect to find at various points in the amplifier circuit. No allowance is made in these illustrations for the differences

in potentials of various portions of the circuit; these diagrams are merely representative of the behavior of the r-f potentials and currents. Notice particularly that the r-f plate voltage is 180 degrees out of phase with the r-f grid voltage. The reason for this is easily understood. When the grid is its at its most positive potential, the plate current is at its maximum. As the plate current is drawn through the load impedance, the increase in plate current causes a corresponding reduction in plate voltage. The plate voltage therefore swings downward at the moment the grid voltage swings upward. We also see that the current in the load resistor is lagging the r-f plate voltage by an angle of a little less than 90 degrees. Correct operation of the tank circuit requires that the resistance of this load resistor be much smaller than the reactance of the coil."

Best regards, Richard Harrison, KB5WZI

You will probably want to center load the antenna for max efficiency (min I**2R loss in the coil at the current node minumum). The length will depend on the frequencies involed and the electrical length of the coil, a subject which sometimes generates debate in this group. For the coil's electrical length, I might suggest using the Corum inductance calculator at

http://hamwaves.com/antennas/inductance.html

It will help if you are handy with a smith chart (an antenna is a lossy transmission line).

For this type of antenna I would stay away from software modeling programs like EZNEC until you first fully understand the electrical model (using corum etc.) and only then to use it as a reference. You will find the smith chart and Corum far more useful than method-of-moments software tabulators.

Richard, I thoroughly enjoyed reading your post above on the analogy between the action of the energy storage of the tank circuit and that of a automobile engine, so I'd like you to read a portion of Chapter 19 from Reflections 2 to see how I approached the same analogy for the book that I quote below:

Therefore, the pi-network must be designed to provide the equivalent optimum resistance RL looking into the input for whatever load terminates the output. The current pulses flowing into the network deliver bursts of electrical energy to the network periodically, in the same manner as the spring-loaded escapement mechanism in the pendulum clock delivers mechanical energy periodically to the swing of the pendulum. In a similar manner, after each plate current pulse enters the pi-network tank curcuit, the flywheel effect of the resonant tank circuit stores the electromagnetic energy delivered by the current pulse, and thus maintains a continuous sinusoidal flow of current throughout the tank, in the same manner as the pendulum swings continuously and periodically after each thrust from the escapement mechanism. The continuous swing of the pendulum results from the inertia of the weight at the end of the pendulum, due to the energy stored in the weight. The path inscribed by the motion of the pendulum is a sine wave, the same as at the output of the amplifier. We will continue the discussion of the flywheel effect in the tank circuit with a more in-depth examination later.

....

We now return to conduct a close examination of the vitally important flywheel effect of the tank circuit. The energy storage (Q) in the tank produces the flywheel effect that isolates the nonlinear pulsed energy entering the tank at the input from the smoothed energy delivered at the output. As a result of this isolation the energy delivered at the output is a smooth sine wave, with linear voltage/current characteristics that support the theorems generally restricted to linear operation. We know that the widely varying voltage/current

relationship at the tank input results in widely varying impedances, which precludes the possibility of a conjugate match at the input of the tank circuit. However, the energy stored in the tank provides constant impedance at the output that supports both the Conjugate Matching and the Maximum Power-transfer Theorems.1

The acceptance by many engineers and amateurs of the notion that the output of the RF tank is nonlinear is a reason some readers will have difficulty in appreciating that the output of the RF tank circuit is linear, and can thus support the conjugate match. Valid analogies between different disciplines are often helpful in clarifying difficulties in appreciating certain aspects of a particular discipline. Fortunately, energy storage in the mechanical discipline has a valid and rigorous analogous relationship with energy storage in LC circuitry that makes it appropriate to draw upon a mechanical example to clarify the effect of energy storage in the RF tank circuit. (A further convincing analogy involving water appears later in the Chapter, in which the origin of the term 'tank circuit' is revealed.)

The smoothing action of the RF energy stored in the tank circuit is rigorously analogous to the smoothing action of the energy stored in the flywheel in the automobile engine. In the automobile engine the flywheel smooths the pulses of energy delivered to the crankshaft by the thrust of the pistons. As in the tank circuit of the amplifier, the automobile flywheel is an energy storage device, and the smoothing of the energy pulses from the pistons is achieved by the energy stored in the flywheel. In effect, it is the flywheel that delivers the energy to the transmission. The energy storage capacity required of the flywheel to deliver smooth energy to the transmission is determined by the number of piston pulses per revolution of the crankshaft. The greater the number of pistons, the less storage capacity is required to achieve a specified level of smoothness in the energy delivered by the flywheel. The storage capacity of the flywheel is determined by its moment of inertia, and the storage capacity of the tank circuit in the RF amplifier is determined by its Q.

Richard, analysis of the Class C amplifier excited with a constant amplitude single frequency sine wave is revealing about their transfer linearity.

I do not disagree that a Class C amplifier excited with a constant amplitude single frequency sine wave driving a resonant load produces a low distortion constant amplitude single frequency sine wave output.

But the absence of harmonic distortion in such an amplifier is not evidence that the amplifier transfer characteristic is linear. You may be able to use harmonic distortion to detect non-linearity in, for example, audio amplifiers... but not in RF amplifiers with a resonant load... for the reasons set out in your quotation.

A Class C amplifier is unsuited to amplfying SSB telephony because it is manifestly non-linear. In fact, a Class C amplifier is so non-linear that it is well suited to use as a relatively efficient harmonic multiplier.

Class B and AB RF amplifiers are extremely sensitive to non-linearity in the region near cut-off and must have sufficient idle current in every active device (which means conduction ange is > 180°) so that distortion products are sufficiently low. This means that the theoretical conduction angle of 180° for Class B is just not realisable because of distortion, much less 120°.

Walt, it wasn't so much that it was long, but it was long and for all that was said, it didn't address the linearity issue.

I understand your position to be that the behaviour of the tank circuit is independent of the transfer linearity of the active device... but asserting that 'things' are linear because there are no harmonics is wrong and being so, is no support for your argument.

I am wary of analogies, the switch analogy that was raised is not a good approximation and I haven't even thought about the car engine.

I am genuinely insterested in your argument. I don't accept it (yet?) as you know, and I have spent some time over the last 18 months or so exploring the concept you describe.

Fundamentally, I am trying to reconcile what you say with the techniques commonly accepted for designing such a PA. Those design techniques give us a method of predicting power output at different load impedances, and the E/I characteristic for different loads is not always a straight line (as it would be if a Thevenin equivalent circuit exists), though it might appear fairly straight over a narrow domain. Since working from characteristic curves is so prone to error, my modelling has been based on an idealised triode transfer characteristic, but with similar behaviour to an 811A. The analysis is waiting for me to build the analytical equations for the negative feedback due to cathode degeneration in a grounded grid configuration. I need to apply more time to it, and the revived discussion might focus me for a bit!

Owen

Hi Owen,

Consult the work of H.W. Bode taken from his lectures at Bell Labs ca. 1939, and then rendered into text as:
Network Analysis and Feedback Amplifier Design,
Chapter IV Mathematical Definition of Feedback
4.2 Return Voltage and Reduction in Effect of Tube Variations p 46
It attends specifically (grounded grid triode) what you call out above.

In a nutshell, Output (or Input) Z can be tailored by what is called the "noise gain" of an amplifier. In today's parlance, that is that portion of Open loop gain that is fed back to the input to create what is called closed loop gain ("noise gain" is simply the difference when all gains are expressed as dB). The higher the "noise gain" the lower the output Z (or higher the input Z) compared to the native (open loop) Z. There are a host of other characteristics improvements that flow from this same boon offered by "noise gain" (dynamic range, noise rejection, linearity, CMRR, PSRR, and so on).

This shorthand can be found expanded in discussion in
5.5 Effect of Feedback on Input and Output Impedances of Amplifiers
bullets 1. through 4. but it serves the reader to really stick with the first 4 chapters to gain the proficiency to tackle the remaining 15 as the text is heavily cross-referential.

The general formula can be found at:
5.11 Exact Formula for External Gain with Feedback (5-30)

Bode was not simply a chalk-and-talk theorist wholly ignorant of the practical realities as are evidenced in several chapter headings:
Chapter VII Stability and Physical Realizability

Chapter IX Physical Representation of Driving Point Impedance Functions

Chapter XI Physical Representation of transfer Impedance Functions

Chapter XIII General Restrictions on Physical Network Characterizations

Ultimately, it takes very little reading applied to the conventional designs found in Amateur class amplifiers to discover there is really very, very little modification of amplifier characteristics offered through negative feedback design (it costs too much). In fact, I would say none whatever - hence the heavy filtering at the outputs and the customers' universal acceptance of barely mediocre performance. It might be said that every transmitter owned by hams is a museum of 1930s performance. And for those who mistake the feedback of stabilization (barely found in those same cheap designs) - this is not negative feedback, it is compensation. It too has scant effect on tailoring (reducing/increasing) impedances.

As I am undoubtedly the only copy holder of this book in this group, access can be obtained through:

http://books.google.com/books?client=firefox-a&um=1&q=H.W.+Bode&btnG=Search+Books
which will provide a surplus of leads, if not the exact title. Some links might provide a pdf, others full access, yet others limited access, and most have links to copies in the market place.

Given the usual confusion over what constitutes a Conjugate match (when most argue an Impedance match in its place) says discussion of "Efficiency and maximum power transfer" without more rigorous resources fails to even reach the level of tepid conjecture.

Bottom line is the source presents a real resistance and no appeal to ratios, linearity, load lines, fly-wheels, or partial cycles is necessary to arrive at a definitive value (which, to this point has been notably absent in the face of obviously localized heat and loss). There is plenty of discussion of what it is NOT, but none seem to know what it IS. That the typical Amateur amplifier source Z is demonstrable is embarrassment enough to this shortfall of expertise. (The pile of theories, books and formulas merely support the obvious, not replace it.)

Hi Gary,

The Comet CA-2x4SR almost makes it with 140-160/435-465 MHz @ less
than 1.5:1.
<http://www.cometantenna.com/products.php?CatID=1&famID=4&childID=4>

You could play around with a conical monopole, sort of like an upside
down discone. Nil-Jon used to sell one.

5437. 40m centre feed dipole, I want to add 80m

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-16 10:19:33 UTC
From: Andy <dx90@blueyounder.co.uk>
Message-ID: <N6r5k.124358$TL1.84245@newsfe21.ams2>
Source record: 24959

Hi,

I have a 40 meter centre feed dipole cut for 40 and feed direct with 50 Ohm coax. The house end is connected to the centre of the coax and the pole end is connected to the braid. Seems to work best this way round.
The antenna is fixed tight to the house and the other end is tight to the metal pole in a straight-line, diagonal across the garden, both ends are insulated. The garden is about 64 feet give or take a couple of feet.

I cannot drop the ends down because of the house and metal pole at the end of the garden being so close. I can only feed the antenna with coax. The neighbours are OK with coax but not the ribbon feeder hanging down and I don't want to upset them if I can help it.

My question. What are my options to enable me to operate 80 and 40m on this same antenna wire?

I've given up on this idea for now. I just can't get any ground wires above
or below ground here at present and the couple of earth rods that I have
sunk in just doesn't do the job.

Andy,

Pretty much any antenna tuning unit (ATU) will work to enable you to use this antenna on 80 metres. Obviously efficiency will suffer, but you will get a signal out. The antenna needs extra length or more inductance to bring it to resonance on 80 metres.

You could experiment with an old metal variable capacitor (around 350 pf) and a two inch diameter coil with about 12 or 15 turns and a fly lead to short out the turns. Old mains wiring cable is a good source of wire for this. Connecting this up in the coax feed in an 'L' configuration will allow a surprising range of frequencies to be brought to resonance on your antenna. Check out Google for some ideas on how to wire it up. A metal air spaced variable should be good for powers up to a hundred watts without arcing problems.

There will probably be a lot of articles about an unbalanced feed causing the coax to radiate. Winding the coax into half a dozen 6-inch turns fastened with cable ties at the feed point of the dipole will help avoid this problem.

Or, you could add a couple of coils, one each side of the dipole centre to increase the physical wire length in the air and bridge out the coils to work at 20 metres, but this would involve raising and lowering the antenna. You could use a couple of relays to perform the job, but it all starts to get rather more complex than simply using an ATU.

Regards

Mike G0ULI

Any,
I think one way is to feed the antenna as a top loaded vertical. What you do is at the end of the coax (the PL259 connector) you short the center to the braid. Then you treat it as a single wire, as if it was the bottom end of a vertical. Use a tuner. You will need a ground on the tuner.
The most optimum arrangement would be for the tuner to be sitting on the earth, right under the centre of the dipole with the coax coming straight down to it, and with a series of radials out all over the ground from the tuner. This will probably not be possible so you start making your compromises from there.

I would consider a switched loading coil at the feedpoint.
Switch it in for 80m and out for 40m.

Two options come to mind, Gary. The first is to find a commercial diplexer that covers your frequency ranges, which is not likely, second is to build a three port diplexer. Google for diplexer, and you find a fair number of designs, many of which could be modified quite easily, I think.

Third, a 1/4 wave antenna at VHF is a 3/4 wave antenna at UHF. Can you make one broadbanded enough to cover? Don't know, but it might be worth trying.

Or, as I used it, that superposition holds.
One can build an amplifier or other device where the Pout(Pin) =straight line, but is not linear in the formal sense. Say you built a widget that measured the input frequency and amplitude, then drove a synthesizer at that frequency and amplitude = 2*input amplitude.

It would not be.You're right

The active device isn't linear.
neither is the whole assembly.

I think, though, that sometimes we take a more casual view of linear (e.g. people talk about the linearity of a log detector.. referring to the deviation from a Voltage out=dBm in straight line.)

And, some confusion about nonlinear devices in a building block that is, by and large, linear (e.g. a power op amp with an AB2 output stage and a fair amount of negative feedback) with some constraints on frequency and amplitude.

Depends on what your regulatory environment is, too...

A 50 foot tower out in the middle of a 160 acre field will typically
require less analysis to meet the local rules than a 100 foot tower on
5000 ft suburban lot.

probably not "every transmitter", but certainly the vast majority of designs, particularly those for HF based on tubes in the ARRL handbook (and by extension, those sold to readers of the handbook).

Cost *is* a factor. The Harris PWM modular transmitters are very cool, but beyond the means of most hams as a commercially manufactured item (in that, the NRE for a consumer mfr to get there would be prohibitively high)

One should also not neglect that the hobby aspect of ham radio provides an incentive (for some) to preserve fine (or not so fine) examples of past radio art. No more unusual than steam train fans or classic auto collectors. There is a visceral satisfaction of seeing those glowing tubes with the plates changing color, notwithstanding that the RF performance, in objective terms, is horrid.

Owen Duffy wrote:
"... but asserting that things are linear because there are no harmonics is wrong and being so, is no support for your atgument."

No one is arguing that an amplitude modulated wave can be amplified by a Class C amplifier stage unimpaired by amplitude distortion.

Terman wrote on page 525 0f his 1955 opus:
"Amplitude distortion exists when the modulation envelope contains frequency components not present in the modulating signal. Thus if the modulating signal is a sine wave, then amplitude distortion will cause the envelope to contain harmonics of the modulating signal, which in turn denotes the presence of high-order sideband components that differ from the carrier frequency by harmonics of the modulating frequency."

I`ve used microwave system performance monitors which alarmed on this principle.

If there are no harmonics there is no distortion no matter how lousy the transfer function. It is legal to filter out noise and distortion.

Best regards, Richard Harrison, KB5WZI

You could get trap dipoles for the 80 and 40m band with almost the
dimensions of a 40m dipol, e.g Diamond W-8010

My antenna book shows a short antenna for 80 and 40m which is called
"Morgain antenna". It was originally produced in the USA.

Owen, I didn't realize that this thread was specific to 'linear transfer characteristic'. I thought the thread topic was sufficiently broad so as to include the subject of linearity of the output of the tank circuit that permits the use of theorems that require the output to be linear. Richard H's and my posts were simply reminders that the energy storage in the tank circuit is the reason for the linear relation between voltage and current at the output of both Class B and C amplifiers that results in a sine wave. From that perspective I believed our posts were legitimate to the thread topic. Apparently we were wrong.

And Owen, I'm somewhat surprised that you don't agree with the flywheel analogy with respect to the smoothing effect of the energy storage in the tank circuit. This analogy has been around for decades--it's not my invention. IMHO, the periodic energy spurts from the pistons entering the flywheel is precisely an analog of the energy spurts of the periodic current pulses entering the tank citcuit. Why do you not agree? Even the pendulum swing is appropriate, because if you trace the position of the pendulum with respect to time you'll discover the trace is a perfect sine wave, while the short spurt of energy supplied by the spring at the beginning of each cycle is just sufficient to overcome the energy dissipated due to friction at the axis plus the aerodynamic resistance. How could this not be an appropriate analogy? Sorry to have forced you away from the thread topic with questions not pertaining to the thread.

I am also curious as to why the subject of 'linear transfer characteristic' with respect to Class C amps was even considered, because the Class C amp has always been known to have a distorted output relative to its input. I would agree that the subject is appropriate when considering Class AB and B amplifiers, but not C.

Yes Jim, I should have written Vout/Vin is linear, that Vout(Vin) has no significant terms higher than first order.

Noting that a single ended Class B or AB amplifier can only be linear when a resonant load or suitable filter is included as part of the system.

Elsewhere it was suggested that I do not accept the 'flywheel' explanation of the tank circuit. That is not true, but it is a limited explanation, simple, and appealing, but limited.

Another explanation is to view the anode current waveform as containing a DC component, a fundamental component and harmonic components and a filter that adequately reduces the undesired components provides the solution to a single ended Class B or AB linear amplifier. The filter is not restricted to a resonant 'tank' circuit.

I have modelled the operating characteristics of my HF linear using 4 572B in AB2. An FFT of the anode current reveals the spectral content, it is plotted at http://www.vk1od.net/lost/572BIaSpectrum.png . Of course, the output filter must only select the fundamental component for linear operation, selection of a harmonic would not be acceptable for a complex input waveform because it would destroy the absolute relationship between different frequency components of the input.

Because Richards statement quoted above (which must be about transfer linearity) is being used to support your assertion that the PA is linear in its terminal V/I response with changing load.

Walt, the thread has become muddled with helpers muddying the water. Your proposition needs to be argued with a single logically developed sound argument. Your Chapter 19 tries to do that.

I have already stated that (as yet?) I am unconvinced, and I make the observation that I am not alone. I will work through resolving the apparent inconsistencies in my own time and without the confusion of whether or not harmonics exist or more correctly the extent to which they exist, and what that might mean.

300 Ohms ribbon twin feeder is hardly more visible than coax feeder .
You don't have to use the 'wide' 450 Ohms ribbon type.
300 Ohms ribbon has an approx velocity factor of 0.8 ,so if you make
half the dipole + the feeder (roughly) an electrical 1/4 -3/4 -etc
wavelength at 80 meters ,you will be home and dry with an appropriate
matching unit or a choke balun in combination with a 'coax-in ,coax-out'
matching box.

Fine.

> It is also true that absence of of harmonics is proof of linearity,

That is not a logical implication of your quote from Terman, it is entirely your statement, and without splitting hairs over the absolute meaning of 'absence', it is wrong when applied to a Class C amplifier with pure sine wave excitation and a resonant load.

The converse is not logically equivalent to the original.

> ...
> I challenge you to prove a mistake in Terman`s writings.

I have no problems with the statement you attribute to Terman and haven't said anything contrary to that during the discussion.

Richard, I accept that you are committed to your view, lets leave it at that. I don't think your statements on the matter support Walt's proposition, rather since they are in my view flawed, I think they weaken the body of evidence.

Hello,
I have downloaded the latest version from

http://www.nerg.asn.au/software.htm

YC52DIST.zip

The program does not run.

When loading any xxxx.yag file and starting to calculate a pattern,
it says:

"Problem with Nec 2 Check Data file SXINFIL.NEC"

When running an Auto Optimize for gain or F/B ratio
the program goes into an endless loop.

Win XP, all updates, and freshly installed VB5 runtimes.
So far my system has sent ~ 100 problem reports to Microsoft :-)

Can anyone help?

Owen, as I view your last paragraph above it seems apparent that you do not believe Richard's and my position that the output of a Class C amplifier can be linear. We're talking about at the 'output', not the 'thruput'. How can you refute the evidence of a nearly pure sine wave at the output terminals of the pi-network?

Walt, you have posted this twice.

There are subtle word shifts here, you are saying "a Class C
amplifier can be linear" rather than is (always) linear.

It is true that a Class C amplifier with resonant load and a constant
amplitude sine wave drive may appear linear when comparing Vout to Vin.

But, as I explained earlier, if you vary the drive amplitude, it is
clearly not linear... in typical cases output will cease below about 25%
of the drive level required for maximum output.

Further, if you drive it with a complex waveform, it is clearly non
linear at any drive level.

Richard's solution to detecting RF PA distortion by monitoring harmonics
is an interesting one, because it suffers the disadvantage of output
filtering masking the harmonics (unless the monitor point was prior to
filtering).

The most widely accepted test for linearity (Vout/Vin) of an RF PA is the
'two tone test', where the drive is a complex waveform (the sum of two
equal amplitude sine waves quite close in frequency) and at least some of
the distortion products due to third order and fifth order etc transfer
terms appears in-band in the output after all output filtering, and where
they can be reliably compared in amplitude to the desired signals. A
Class C RF PA will not appear to be linear under such a test at any drive
level.

I suspect that the issue of transfer linearity is a red herring to your
proposition about the Thevenin equivalent of an RF PA, but if you do
depend on arguing that the transfer characteristic of a Class C RF PA is
linear, I think you are on shaky ground.

Owen

Owen, with a Class C amplifier biased beyond cutoff the grid is never going to see a constant amplitude sine wave, even if the constant amplitude sine wave were impressed on the grid. How then can the transfer linearity ever occur under these conditions? I maintain that it cannot.

Owen, you are either twisting my words, or you're not listening. I've made it very clear that I'm NOT talking about 'transfer linearity', and never have. My position is only that the OUTPUT of the pi-network is linear. The linearity at the output is irrelevant to the waveform at the input of the tank circuit in Class C amplifiers. I don't even understand why the discussion concerning 'transfer linearity' with respect to Class C amplifiers should have come up.

Walt, W2DU

PS--I didn't send two identical emails--something must have happened at the server to have caused it.

Owen is "throwing in the towel' but not admitting error.

I have no allegiance to a particular view. I am happy to view things from another`s perspective. Owen mught do the same.

Owen Duffy also wrote:
"I understand your position to be that the behavior of a tank circuit is independent of the transfer linearity of the active device...but asserting that things are linear because there are no harmonics is wrong and saying so is no support for your argument."

Owen has it wrong. The final amplifier is linear because its output is an exact replica of its input except for amplitude, or close enough so.

When the waveshape of the output signal from an amplifier varies in any respect other than amplitude from the waveshape of the signal feeding the amplifier, the amplifier is distorting the signal.

Sinewave a-c is considered the perfect waveform. It consists of a single frequency. Any other waveform consists of more than one frequency, So the presence or absence of harmonics in addition to the fundamental is a clear indication of distortion. Anyone can confirm waveform using an oscilloscope.

Best regards, Richard Harrison, KB5WZI

Actually, in modern systems with very complex signals, there are more meaningful tests like noise power ratio with a notch that look for spectral regrowth. The two tone test has the advantage of being moderately easy to perform for middling performance amplifiers/devices. But if you're looking for very high performance, such things as generating the two tones without one generator interfering with the other get to be challenging.

I don't know that the concept of a Thevenin equivalent (a linear circuit theory concept) really has applicability to "box level" models, except over a very restricted range, where one can wave one's hands and ignore the nonlinearities as irrelevant to the question at issue. Sure, over a restricted dynamic range and bandwidth and restricted class of input signals, a Class C (or class E or Class F or E/F1, or a fancy EER system) can be adequately modeled as a linear ideal amplifier.

The real question is what is the value of that model. If the model provides conceptual understanding of some underlying problem, great. For instance, it might help with a link budget. If the model helps design a better amplifier, great. The model might allow prediction of behavior; so that you can, for instance, detect a fault by the difference between model and actual observation, as Richard mentioned with the harmonic energy detector.

Hi Richard,

This is a presumption that is either not in evidence, or it is forced by the necessity of your argument. Consider:

>When the waveshape of the output signal from an amplifier varies in any >respect other than amplitude from the waveshape of the signal feeding >the amplifier, the amplifier is distorting the signal.

The presumption (forced, or otherwise) is that the input is sinusoidal. In fact, the cathode current of the amplifier proves quite positively that only a pulse in, 120 degrees of the sinewave, or even less, is sufficient to generate a remarkably clean sinewave at the final's output.

Simply put, a pulse with a 33% duty cycle, and having sufficient amplitude (and steep skirts) would present an output that was wholly non-linear in relation to the pulse excitation. Looking only at the output, you couldn't possibly say if the input was a complete 360 degrees of sine wave, or 33% DC of a rectangular wave. Not unless new constraints are added that push the argument away from current issues.

To extend an analogy, the circular motion of the car's wheels prove there is a non-linear relationship to the explosion of the gas mixture in the compression cylinder.

Or to further decimate the argument, an oscillator produces as pure a signal to no input at all (barring the excitation of noise that engenders a selectively reinforced oscillation).

But the debate over linearity is window dressing to answering the practical question:
What is the source resistance of any power amplifier?

I am not interested in the values that are NOT the source resistance. I am content that those who have not responded to this specific and observable characteristic don't know. However, given the thrashing of this topic, someone (besides me) should.

Hi there,
Anyone have or used one of these antenna tuners?

Wondering how they perform, have read the reviews on eham ect, just looking for other opinions.

TIA
Richard

I agree with you. I am not implying that you cannot design a PA with
controlled equivalent source impedance, but you don't do they way most
ham PAs are designed.

As I understand it, Walt's proposition is that the Thevinin equivalent
source impedance (at the device terminals) of the PA is equal to the
conjugate of Zl (at the device terminals) as a consequence of adjustment
of the PA for maximum power output, a twist on the Jacobi MPT theorem.
For that model to be generally useful in explaining behaviour of the PA
in the presense of 'reflections', it would need to be true for a wide
range of load impedances.

I think it goes to whether Walt's proposition and observations apply in general, and then a valid explanation for what happens.

From _Filtering in the Time and Frequency Domains_ by Herman J.
Blinchikov and Anatol I. Zverev: "A system is linear if the input
c1f1(t)+ c2f2(t) produces and output c1g1(t)+ c2g2(t) for all
f1(t) and f2(t), when it is known that an input f1(t) produces an
output g1(t) and an input f2(t) produces and output g2(t). The c1 and
c2 are arbitrary constants but may be complex numbers. This property of
superposition is characteristic of linear systems." You're ignoring the
addition part of the concept of linearity, Richard. Moreover, the
functions f1(t) and f2(t) don't have to be sine waves; the concept
is more general than that. Finally, read Richard Clark's post.
A sine wave out doesn't prove a sine wave in.

That is a remarkably clear statement of the behavior of a Class C amplifier. The amplifier acts as a generator of a sinewave which is synchronized by its input signal instead of being an accurate reproducer of the waveform at its input.

The less than half wave of current flow of the Class C amplifier allows an efficiency exceeding 50%. Walt Maxwell`s tests show that the Class C amplifier sticks to the parameters of a Thevenin source.

The question of "what is the source impedance" presented to a load by the amplifier? is answered, not by magic, but by the maximum power transfer theorem. The amplifier must be adjusted to deliver all its available power. Then, the output impedance of the amplifier is simply the conjugate of the load impedance which is easily measured.

Best regards, Richard Harrison, KB5WZI

Ian,
They probably are adequate for 'just listening'. In a lot of cases,
not using a ground works just fine too. Just depends on the
circumstances. Receivers just don't seem to be very 'picky' like
transmitters are. Since the 'ground' can sort of affect where you
hear things from, that's one of those 'things' to consider too.
There are very few 'perfect' antennas or installations, almost all of
them are a compromise in some way. The idea is to make the best of
what you got (Ooooo, is that a can of worms!:)). And the mostest
important thingy is to have fun at it.

Hi Richard,

MPT <> Conjugate Match <> Z Match

You can NOT achieve the COMBINATION of any two, much less all three with a Class C amplifier. This is like checking all three possible answers on a multiple choice exam. It follows that source impedance has not been answered here as a qualifiable (which is certainly not what I was looking for).

I will take it that you don't know what the source impedance is as a quantifiable either. That is, unless you unwind all the confounding statements and remove those in error. There cannot be three, simultaneous quantifiables of differing values.

Richard,
Considering some of the reviews I've seen on various forums, the one thing those reviews proves is that they must work. How well they work just depends on how close to the tuner's limits any particular antenna falls. 'Size' is one consideration that isn't thought of very often. Bigger usually means larger limits cuz all those thingys inside are larger, which is good to some ridiculous point. Deciding where 'ridiculous' starts/stops depends on you to a large extent. It has to do with the antennas you have/want/are allowed, and the size of your bank account.
Is it the mostest best thing on the market? Good question, and another one of those 'depends' thingys. (Mine is the bestest tuner ever made. It isn't produced anymore. It is not for sale, wish I had another one! Can do some really 'weird' antennas. Ain't saying what it is so the price will be cheaper when I find another one.)

Owen, on whether my observations apply in general, if you re-read the summarizing paragraph on my Chapter 19A you'll see that I've made measurements of the source impedance of two different xmtrs with several different complex impedance loads. All measurements showed the source impedance equal to the load impedance when all available power is delivered to the load.

As to the explanation, Richard H said it well. When all available power is delivered, according to the maximum power transfer theorem the source impedance equals the load impedance. My measurements have proved this to be true in determining the source impedance of the xmtrs I measured.

Hi Richard C,

Am I hearing you correctly? Are you disagreeing with Richard H? Are you saying that maximum power transfer, conjugate match at the output, and Z match cannot occur simultaneously? Are you serious? As I understand Everitt's statement of the maximum-power-transfer theorem, when the maximum available power is being transferred to the load there is a conjugate match. Does this not also mean there is a 'Z' match? Can't 'Z' be assumed to be the impedance of the source as well as the load?

Richard,

My Palstar AT1KP arrived this morning, so early days yet.
What I can say about it is that the build quality inside and out looks
excellent.
I have only run 110 watts through it and it has tuned my 40m Centre Fed
Dipole cut for 40 meters down to 1.1: from 1.8 - 6 meters with ease.

Hope this helps.

Hi Walt,

For a Class C tube amplifier.

All descriptions of tune-up for a Class C tube amplifier describe a
qualitative MPT as this classic method offers absolutely no
information about the quantitative degree of initial mismatch, nor
subsequent proximate match. In other words, there are no quantitative
values of load impedance revealed by this method. It may even be said
that the classic tune-up only describes "an attempt" at MPT; as it
may, in fact, not even achieve anything more than Mediocre Power
Transfer. After peaking the grid and dipping the plate, I have
observed many different peaks and dips for many various loads to know
that not all loads obtained all available power.

The classic description of a tune-up is based on qualitative
assumptions and the amplifier is brought into its best attempt, which
is not demonstrably efficient, nor even proven to be "matched"
conjugately or by impedance. This takes more information (so far
unrevealed) obtained by current into the known load (unrevealed), and
power into the source (unrevealed). No one other than myself has
expressed the loss of the source because no one else has ever
enumerated its resistance (a topic commonly hedged and avoided) Hence
discussion of efficiency is lost in the woods and correlation to
MPT/Z/Conjugation is equally doomed to ambiguity.

>Are you serious? As I understand Everitt's statement of

Everitt notwithstanding, Lord Kelvin trumps him with
"when you cannot express it in numbers, your knowledge is of a
meagre and unsatisfactory kind"
This thread has suffered from a lack of measurables that are not that
difficult to obtain.

So, to return to my very specific question:
What is the source resistance of any power amplifier?
I will further loosen constraints (if that isn't loose enough)
For any match?

One complex number is sufficient, and certainly that value will
resolve all imponderabilities is what I am asking for.

That's the way I understand it too, Richard. But also works in the opposite direction too, by adjusting the source impedance to have the same magnitude and opposite phase of the load impedance. This is the procedure I used to prove the value of the source impedance.

I'm having loads of fun since I started.

I recently purchased an RigExpert AA-200 Antenna Anal;yser from Radio World.
Here's the link if anyone wants a read.
http://www.radioworld.co.uk/~radio/catalog/aa200-antenna-analyzer-p-5841.html?osCsid=a223fcdeb781abc7dba4a96691a21039

Trouble now is I can't put the AA-200 down with out thinking of some thing
else to try out. I'm getting addicted.

Richard, are you inferring that I have not submitted the measurables required to determine the source impedances of the xmtrs I measured? What additional measureables that I haven't already submitted are you asking for to prove the source impedances that I've already submitted are valid?

> So, to return to my very specific question:
> What is the source resistance of any power amplifier?

Richard, the source impedance of one of the xmtrs I measured with load impedance of 17.98 + j8.77 ohms measured 18 - j8 ohms. Considering measurement error, wouldn't you agree that these two impedances qualify for a conjugate match, and that this value of source impedance is valid at least within the realm of possibility?

For any match?
>
> One complex number is sufficient, and certainly that value will

Source record: 24814

Richard Clark wrote:
"What is the source resistance of any power amplifier?"

Most power amplifiers are designed for a specified load but include controls to adjust their outputs, both resistance and reactance, so that a load which deviates can be made to match the 50-ohm or 600-ohm load specified for the transmitter.

Am broadcast stations in the USA have a point at the transmitter output just before power branches out to antenna system elements called the "common point". Impedance here has been adjusted to a specified resistance and a thermocouple ammeter is routinely installed which is used to determine that the specified power output is being delivered by the station by I squared R according to the FCC allocation. There is a multiplier specified of 0.92 for stations of 5 KW or less. For stations more powerful than 5 KW the multiplier is 0.947. This multiplier allows for a slight increase in power to offset misc. errors and losses.

John E. Cunningham writes in "The Complete Broadcast Antenna Book" on page 51:
"Suppose for example, we have a transmitter that is designed to work into a 50-ohm load at an efficiency of 70% (Fig. 1-26). The efficiency of this circuit expressed as a decimal, is given by

eff = RL / RS + RL

Rearranging

RS = RL [1/eff - 1]

Substituting the numbers inti this, we get

RS = 50 [1/0.7 - 1] = 50(1/0,7 - 1) = 50(0.43) = 21.4 ohms

You have an example in numbers. Hope you are happy.

Best regards, Richard Harrison, KB5WZI

Hi Walt,

It is more direct and responsive to every request I've made for
anything from anyone else so far. However, I presume it is the value
at the antenna connections of the amplifier that transforms through
the plate tuning toward the plate itself to render something more like
Rp (several KOhms?). Is it from a direct measurement, or by inference
to the load and tuning adjustments?

Rp has nothing to do with a Class C amplifier which acts like a switch presenting an impedance to average current flow by being open-circuit most of the time.

Hi Richard,

As I mentioned to Walt in similar response to my oft-asked question: direct and to the point. I see no others yet.

I know this wasn't arrived at by direct measurement and only by inference. As I remarked to Walt (but in the inverse), I presume this value is that transformed through the plate tuning from the plate's Rp? Can you provide some work-up (presumably several KOhms) from your citation for that?

Hi Richard,

You have no answer to what 18 - j8 ohms transforms to back through plate tuning towards the plate. It is not responsive in kind.

As this operation is a commonplace of any treatment on the subject of amplifier design (consult Bode, et al), then your ambiguous response is outside of the canon of engineering.

I would intuit that you depart from Walt in this regard, and that he will have a quantitative answer.

Richard, am I now to understand that you haven't reviewed my Chapter 19A, which details the entire procedure I used for the measurements that include the resistance RL = 1400 ohms at the input of the pi-network? If you haven't I can understand the reasons for your questions. I urge you to read 'Section 19.14 Additional Experimental Data', the last portion of the Chapter which describes in detail the procedure is used in the measurements made on a Kenwood TS-830S. I'm sure you'll find the answers you're looking for there.

You can find 19A by using this url from Cecil, http://www.w5dxp.com/Chapt19a.doc. It derives from the thread directly above 'Unwin Antennas'.

Hi Walt,

As I expected, you can provide quantitative data. This is a
refreshing change from the, what?, 100+ postings of "thoughts" on the
matter? It would suggest a poor rate of exchange for thinking these
days to come to so little conclusion.

>You can find 19A by using this url from Cecil,
>http://www.w5dxp.com/Chapt19a.doc.

Well, if you posted it through Cecil here, yes I didn't see it as I
don't read him.

Now, however, having a copy of that work from your own web site (why
didn't you reference that?) that I got after my last post, I will go
through it by the steps you lay out so carefully.

http://www.w2du.com/r3ch19a.pdf

Before doing so, and confining that to a separate posting, I would say
that I can acknowledge your fine work and care at creating a protocol
that does seem to reduce the variables, and test your hypothesis
without editorial bias. It seems like a great improvement from
earlier attempts to tackle the same issue.

A preliminary thought, however: What would you say is the Q of the
plate tank, Plate to Load, during operation under each load?

Source record: 24823

I've built a VHF/UHF Log Periodic for monitoring. It works quite well, but I've been curious about one thing... Using an analyzer, I get a good SWR on the majority of the antenna (below 1.5), but there's some areas that are fairly high. Well above 3.0. Obviously this isn't crucial for just monitoring, but I use that as a guide as far as seeing how well the antenna is designed. The thing that I don't understand is that the SWR readings will change if the cable is moved. The cable comes off the front end of the boom, travels back to the middle, then comes off across a horizontal mast (the antenna is vertical) and down the vertical mast. All that part of the cable doesn't move... But if I pick up the cable on the ground and change the location a bit, the SWR will change quite a bit... Areas that before had a poor SWR now have a good one, and areas that were good change to poor. Why would this happen? Also, would using a longer cable possibly make the SWR better? Typically I have tested with a 20' RG8X cable. I also usually test with the antenna about 8' off the ground. Would it improve with better elevation off the ground as well?

Thanks for any ideas.

Thin rods are kind of tricky.. they have a drag that is much more than one would expect from their cross-sectional area, depending on the diameter and wind speed (i.e. the Reynolds number). Cd could be anywhere from 0.4 to almost 2.0

(this is the aerodynamic curse that afflicts old planes using exposed wires as structural members)

> Hi Dave
>
> What type balun did you use?

'Tis a good question!

If an antenna's measured SWR changes when the doax is moved, it tends to mean one of two things: either there's something physically loose which is causing an intermittent electrical connnection, or you have a significant amount of RF current flowing back down the outside of the coax, and the feedline is acting as part of the antenna.

I suspect that your high-SWR points are at frequencies where the outside of the feedline is close to a multiple of 1/2 electrical wavelength, and appears as a relatively low RF impedance to ground. Changing the feedline position or length could shift the effect of this unwanted RF pathway and move the high-SWR frequencies around.

It's also possible that your SWR meter isn't actually measuring what you think it's measuring. If there's a strong UHF/VHF signal being transmitted in your area, the feedline or antenna might be picking it up and it might be confusing your analyzer (MFJ analyzers are notoriously subject to confusion on the lower HF frequencies for this reason, and you might be having a similar problem at VHF/UHF).

Using a good balun (with the correct impedance-transformation ratio) at the feedpoint may help matters, if you aren't doing this already.

Equally likely to help would be adding some choking impedance to the feedline, in the form of one-or-a-few snap-on two-part ferrite "interference suppressor" chokes. I'd suggest installing one just below the point at which the feedline leaves the antenna boom.

I suspect that choking the feedline will make the wonky SWR measurement settle down.

And, yes, adding a longer feedline will probably reduce the SWR weirdness (or at least move it around to different frequencies), but it's not a particularly good solution to the problem... you'd probably have to add a lot of coax (and thus a lot of unwanted losses) in order to reduce the SWR excursions by much.

Hi Dave Platt

I suspect the original Dave has mounted the antenna so the dipoles are
parallel with the mast. And it wasnt clear that he'd taken into account
the need for some sort of a device to allow a balanced antenna to an
unbalanced line. It seemed like a good 'starting question'.
By my analysis, the LPDA is a set of dipoles fed from one end so it tends
to create a pattern null in the direction toward the dipoles from the feed
end. Those dipoles which are too short or too long to be well matched to
the line wont radiate enough to upset the null depth. If the feed line and
tower are coupled to only one half of the dipoles some unbalance is
expected.

Hi Walt -

I have skimmed through it. It seems to me that your arguments with
this person named Bruene should be left out of it. Still, I have
enough faith in your considerable engineering talents (and enough

understanding of the underlying physics) to know that nothing in your results would reveal dissipationless resistors having finite ohmic resistance.

On the other hand, a virtual resistor, being the real component of a virtual impedance, should by definition not be allowed the ability to dissipate (or for that matter, reflect) energy. ;-)

Thanks guys... Up until now I hadn't used a Balun. Not to open the balun debate, but I haven't used one on other versions I've done and everything was fine. The testing I did was out in the middle of nowhere, so that limits the chance of their being an outside signal influence. Jerry, if you were asking if the whole antenna is isolated from the mast... it is. There's no electrical contact between the antenna and any part of the mast. The antenna is supported by a thin horizontal 12" mast to the side of the boom. The antenna is isolated from that part as well. So that holds the antenna about 12" away from the parallel vertical mast. I actually put one up at a friends house today. Interestingly enough it was doing the same thing on the ground as the other one. But when we got it up on the mast about 10' off the roof, the SWR was excellent across the whole designed bandwidth. So I don't know, maybe something as simple as proximity to the ground? Like I said, it's not a big issue for just receiving, but it just kind of bugs me. Then of course, as you mentioned, there's the analyzer itself. But I'd think if it was an error in that, it would just stay the same... Not change by moving the coax.

Hi Dave

I did misunderstand about your mount. But, if the vertical antenna is
supported by a 12 inch horizontal mast, I wouldnt expect the support to
effect the radiation. But, when coax is used to feed a balanced antenna,
some sort of device is recommended to minimize conducting currents along the
Outside of the coax. One method of gfeeding a Log Periodic is to run the
coax inside one of the two tubes that form the parallel line connecting the
dipoles.

Hi Richard,

Just an update for you on my AT1KP tuner.
I am only running 110 watts through the tuner due to not owning an
Amplifier.
I have tried it out on an End Fed wire WITH an earth ground rod that has a
very poor ground and also an End Fed Zep. It still tunes these wires down
to 1.1:1 from 160 - 6 Meters with ease.
I am very pleased with it and I'm glade I purchased the AT1KP. Hope this
helps.

Andy, is your endfed wire the one in your other thread of the 8th June
(ie the 80 Meter End Fed, fed with coax at the far end)? If so,
presumably the tuner is at the shack end. Or are you feeding it from the
shack end.

Hi Ian,

Yes its the same. The tuner is at the shack end (house) and I'm feeding the antenna with 50 Ohm RG-58 C/U coax at the far end of the garden. If I can get it working well I will replace it with some RG-213 that I have here. I put it back up yesterday and started experimenting again.

The End Fed at the moment has 15 feet of 300 Ohm slotted ribbon feeder. This is all I had left spare. One side is connected to the wire antenna and the other side left, not connected. The coax is connected to the 300 Ohm at the bottom and the braid side is now connected to the unconnected side of the 300 Ohm and also to the earth ground rod.
On 80 the receive is up 2-4 S points compared with the 40m coax Centre Fed Dipole. I have not had chance to get any actual reports on 80 yet. Maybe this weekend.

Hi Richard,

Sorry for the delay in answering, we were out of town all day yesterday so this is the first opportunity I've had to read your post. Thank you for your kind assessment of my measurements.

Now to the reason I didn't direct you to my own web page for the file 19A. That version is about two years old, and I have made some sigificant changes since then. Son Rick is my webmaster and at the time he was too busy to update the file on the web page, so I gave Cecil the copy for him to put on his web page. However, instead of adding it to this thread, for some reason he started a new thread.

In addition to that I'm a dim-witted jerk. When I told you about accessing 19A I was very tired and sleepy, so it didn't occur to me until the next morning that I should have simply emailed you the most recent version. I've added some more material even since the version I gave to Cecil, but not in the section reporting the measurements.

Richard, I don't know of any way to determine the Q with the data I obtained, I'd have to think about any additional measurements that would give the Q. Unfortunately, my lab is in Florida and Jean and I are at our Summer home in Mt. Pleasant, MI, so there is no way I can work on the Q until we return to FL in November.

I'd appreciate any further comments you might have on the data appearing in 19A.

Walt, W2DU

No, thanks. Yahoo groups are NOT the same as Usenet or a reasonable substitute for international newsgroups with nntp feeds. A better alternative at the moment are alternate newsfeeds like giganews.

OK, Andy. Noted.

I don't know if you will really improve things by using the 15 foot of
300 ohm feeder. It's a sort of a zepp, but with one side of the twin
feeder earthed. I would try disconnecting the earthed ('unconnected')
side from earth / coax braid. You can either leave it floating, or
connect it to the coax inner. It will then be approximately a
quarterwave on 20m, fed in parallel with the long wire.

Don't read too much into the excellent SWR you're getting with the tuner. That's what the TX sees, but the tuner can't affect the SWR on the aerial feeder. If the coax SWR is sky high (and it can be if the impedance at aerial feed point is high), the coax losses will be much more that you would get compared with when it is matched correctly. You only get away with it by using the lowest-loss you can find, and keeping the coax as short as possible.

I'm not surprised that 80m on the endfed is a bit better than the 40m dipole. But what's 40m like on the endfed? That's when the feed impedance (and coax SWR) will be very high, and where the RG-213 might perform better noticeably better than the RG-58.

As I think I said before, although I am an advocate of simply using coax (regardless), after all these years I am considering in investing in something like a SG230 remote tuner for the far end of the coax.

Hi Walt,

Well, I've put a lot of water under the bridge on the 19A at your web
site. If the comments I make on this version are answered in your
most recent one - all good and well. If not, then that will take care
of itself too. I will be starting a new thread when I've shook out
all the surplus commas in my review.

That may take some time because I'm currently assembling a fundraising
presentation for a non-profit.

While "flamers" are an annoyance and an embarrassment to the human race,
I much prefer them to any possible infringement on anyones "voice."
They are a necessary evil ... but, having the groups available, which
you have mentioned, is good!

Well said.

However the low bandwidth requirements of newsgroups should be included
in any decent ISPs' services, IMHO.

Low bandwidth my ass, a full USENET feed is gigabytes per day.

Know nothing fool.

Gigs? Huh, you find that scary? A simple download of one CD is
generally around ~713 megabytes--on a decent feed this only takes a
matter of minutes ...

That is one problem which has plagued 99% of amateurs--small thinking.

A full T1 line is 1.5 megabits/sec.

The theoretical maximum bandwidth of DSL is 8 megabits/sec and you
will be lucky to get 6 megabits/sec.

A full USENET feed, one way, is about 130 GB day.

130 Gbytes X 8 bits = 1 X 10^12 bits.

1 X 10^12 bits / 6 X 10^6 bit/sec = 1.6 X 10^5 seconds = 46 hours.

So since there are only 24 hours in a day, you need the equivelant of
2 full, good DSL connections just to handle the incoming feed.

Add to the connections necessary for the outgoing feed.

And to store 30 days worth is 4 terabytes of storage.

As I said, know nothing fool.

BTW, how you can read my post when you've plonked me so many times?

5531. Chapter 19A from "Reflections III" - Step Reviews Overview

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:45:42 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <98tq545e2fj84jqu5sjve82langijsmtov@4ax.com>
Source record: 24753

Hi All,

This is simply a quick overview from the separate threads that will follow, each thread devoted to only one Step in the progression of measurements Steps offered by Walt Maxwell in his upcoming release of "Reflections III," Chapter 19A in particular.

I have been working off of three revisions of this work, and some quotes may not be accurate. I will leave reconciliation of those to others as this has been a long and exhaustive examination, and I don't perceive any substantive issues shifted along the way. Not all steps will be critiqued as not all contain response beyond my noting they contained simple reports of fact that did not merit challenging. A full article length version containing all discussion of this will be available.

The discussion threads follow immediately.

5532. Chapter 19A from "Reflections III" - Step 1 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:46:18 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <v4tq54ph4k6lurvrlksthsfl5jmdr49ck3@4ax.com>
Source record: 24754

Step 1.
Using a Kenwood TS-830S transceiver as the RF source, the tuning and loading of the pi-network are adjusted to deliver all the available power into a 50 + j0-ohm load with the grid drive adjusted to deliver the maximum of 100 watts at 4 MHz, thus establishing the area of the RF power window at the input of the pi-network, resistance RLP at the plate, and the slope of the load line. The output source resistance of the amplifier in this condition will later be shown to be 50 ohms. In this condition the DC plate voltage is 800 v and plate current is 260 ma. DC input power is therefore 800 v ? 0.26 a = 208 w. Readings on the Bird 43 wattmeter indicate 100 watts forward and zero watts reflected. (100 watts is the maximum RF output power available at this drive level.) From here on the grid drive is left undisturbed, and the pi-network controls are left undisturbed until Step 10.

There are several points in response here:
1.The load specification (50 + j0-ohm) is for full output power, not some portion of it. This is a minor point.
2.Maximum power from a TS-830S can be as high as 120W, could be lower depending on finals' service life. This is a minor point.
3.Rated typical Plate Current for the 6146B is 220mA. Running more at higher voltage (typical is 750V) to obtain less power sounds like the amp is being strained to produce 100W.
4.ï¿½Available Powerï¿½ is 208W. Efficiency and other considerations certainly lower this, but it would appear that efficiency has been red-lined at 48% by this step's assertions. The red-line at 48% efficiency may reveal the aforementioned strain.

73's
Richard Clark, KB7QHC

5533. Chapter 19A from "Reflections III" - Step 2 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:47:13 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <eltq54di8i0p6b0u8alqjgemd32mgagldp@4ax.com>
Source record: 24755

Step 2.
The amplifier is now powered down and the load resistance RL is measured across the input terminals of the resonant pi-network tank circuit (from plate to ground) with an HP-4815 Vector Impedance Meter. The resistance is found to be approximately 1400 ohms. Because the amplifier was adjusted to deliver the maximum available power of 100 watts prior to the resistance measurement, resistance RLP looking into the plate (upstream from the network terminals) is also approximately 1400 ohms. Accordingly, a non-reactive 1400-ohm resistor is now connected across the input terminals of the pi-network tank circuit and source resistance ROS is measured looking rearward into the output terminals of the network. Resistance ROS was found to be 50 ohms.

Points in response:
1.This is actually two steps: one measurement made from the plate looking towards the load; one measurement made from the output jack looking towards plate.
2.The measurement at the plate without a powered tube unloads the Q of the plate tuning. Does this unloaded Q present a false reading of the transformed load resistance?
3.The load line with 800 v / 0.26 a / 2 = 1539 Ohms.
4.ï¿½Maximum Available Powerï¿½ has not been established, only arrived at by inference. It could be more, it could be less. Being less is unlikely given the subsequent demonstrated power delivered to the load being 100W; but it is suspect that exactly 100W is all that could be obtained. The point, however, is that such attention to ï¿½Available Powerï¿½ is an unnecessary elaboration to the point of taking these steps.
5.The measurement at the output towards the plate similarly unloads the plate tuning Q when the 50 Ohms is removed to make the measurement. Does this unloaded Q present a false reading of the transformed plate resistance?
6.The measurements made in both directions confirm the capacity of an unloaded circuit to perform the transformations in a symmetric fashion (a good test), but you have not tested if the issue of loaded Q is a factor or not. If you were to replace the 1400 Ohm resistor at the plate tuning input (at the plate connection) with a 1000 Ohm resistor, would the 50 Ohms follow that shift? By how much?

73's
Richard Clark, KB7QHC

5534. Chapter 19A from "Reflections III" - Step 7 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:48:50 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <5ntq54dgkttqqc2ppl0g0mn7tk70o6ah4b@4ax.com>
Source record: 24756

Step 7.
Due to the 2.88:1 mismatch at the load, neglecting network losses and the small change in plate current resulting from the mismatch, approximately the same mismatch appears between RLP and ZL at the input of the pi-network. Consequently, the change in load impedance changed the network input resistance RL from 1400 ohms to complex ZL ï¿½ 800 ï¿½ j1000 ohms, measured with the Vector Impedance Meter using the method described in Step 2. To verify the impedance measurement of ZL the phase delay of the network was measured using an HP-8405 Vector Voltmeter and found to be 127ï¿½. Using this value of phase delay the input impedance ZL was calculated using two different methods; one yielding 792 ï¿½ j1003 ohms, the other yielding 794.6 ï¿½ j961.3 ohms, thus verifying the accuracy of the measurement. However, because grid voltage EC, grid drive Eg, and plate voltage EB are left unchanged, resistance RLP at the plate has remained at approximately 1400 ohms, leaving a mismatch between RLP and ZL at the input of the pi-network. As stated above, this value of ZL yields the substantially the same mismatch to plate resistance RLP as that between the output impedance of the pi-network and the 17.98 + j8.77-ohm load, i.e., 2.88:1. This mismatch at the network input results in less power delivered into the network, and thus to the load, a decrease in the area of the RF window at the network input, and a change in the slope of the loadline. (It must be remembered that the input and output mismatches contribute only to mismatch loss, which does not result in power delivered and then lost somewhere in dissipation. As we will see in Step 8, the mismatch at the input of the pi-network results only in a reduced delivery of source power proportional to the degree of mismatch.)

Points in response:
1.We enter into a key remark in the first sentence: neglecting network losses and the small change in plate current resulting from the mismatch. By this statement the subordinate thesis being offered: output source resistance of the RF power amplifier is non-dissipative is wholly invalidated. The observation that the plate current changes (and presumably plate voltage has not, unconfirmed in the protocol) through the agency of mismatch must necessarily admit that the plate resistance has also changed if only because it has been explicitly admitted to through the dismissed current change.
2.To whatever degree (as dictated by the phase of the mismatch), plate dissipation must also change. This is the common experience of literally thousands of Amateur radio operators and has been commented upon and reported for generations when through the unfortunate aspect of phase, it becomes a destructive dissipation. Such reports often attain dramatic legendary status, if only for the afflicted amplifier

owner (who may enjoy comedic celebrity among his peers).
3.Moving on to subsequent sentences, the reported values of complex load resistance (792 ï¿½ j1003 Ohms) seen from the plate looking through tuning towards the new, mismatched load confirms that the plate resistance must be impacted. If, as reported, the plate resistance remains at 1400 Ohms, then there is a mismatch which is admitted to in the text of the original. The final argument is based upon mismatch loss, which from the perspective of the load, is that amount of power not seen, but not lost by dissipation. That much is true from the perspective of the load. The same would be true if we replaced the plate tuning with a large resistor which would also reduce power to the load, so such an appeal has nothing to do with the argument of the subordinate thesis: output source resistance of the RF power amplifier is non-dissipative. The nature of this particular plate mismatch affirms the current indication, and rejects the conclusion of non-dissipation (which is characteristically, and artificially constrained to being exothermic when through phasing it could as easily be endothermic).
4.A more careful protocol would allow for phase by lengthening the 13.5ï¿½ length of coax to 103.5ï¿½ (or more but well less than 180ï¿½) and carefully noting the new plate current. In fact, other lengths should be used to draw a more rigorous correlation.

73's
Richard Clark, KB7QHC

5535. Chapter 19A from "Reflections III" - Step 8 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:50:04 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <0rtq54d2f17ac0la9miis1uppugf31mts9@4ax.com>
Source record: 24757

Step 8.
Readings on a Bird 43 power meter now indicate 95w forward and 20w reflected, meaning only 75 watts are now delivered by the source and absorbed in the mismatched load. The 20w reflected power remains in the coax, and adds to the 75 watts delivered by the source to establish the total forward power of 95w.

Point in response:
The Bird 43 indications only reveal mismatch loss (unstated as 5W if we are to return to the concept of Available Power, which as a rhetorical point has been uncharacteristically discarded) which is only tangentially related to the subordinate thesis: output source resistance of the RF power amplifier is non-dissipative. Step 7 is sufficient to illustrate the thesis.

73's
Richard Clark, KB7QHC

5536. Chapter 19A from "Reflections III" - Step 9 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:50:57 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <estq545vtpgu7buhqajnggvcj1ablil1mj@4ax.com>
Source record: 24758

Step 9.
We now compare the measured power delivered with the calculated power, using the power transmission coefficient, 1 ï¿½ ?2. The calculated power delivered is: 100w ï¿½ (1 ï¿½ ?2) = 76.6w, compared to the 75w indicated by the Bird wattmeter. However, because the new load impedance is less than the original 50 ohms, and also reactive, the amplifier is now overloaded and the pi-network is detuned from resonance. Consequently, the plate current has increased from 260 to 290 ma, plate voltage has dropped to 760 v, and DC input power has increased from 208 w to 220.4 w.

Points in response:
1.This is a surprising departure from reporting in the progression of the protocol. We now find current and voltage reports where formerly they were either dismissed or neglected. However, we will take these as they are reported here.
2.It appears that the calculated power and the reported power agree, this is not directly expressed, but neither these remarks are not stated as being in conflict. Given the editorialization that inhabits the protocol in general, these remarks are remarkably dry and unconnected.
3.Following, with the editorial comment that the amplifier is now overloaded, the connotation is necessarily a rejection of the thesis: output source resistance of the RF power amplifier is non-dissipative; otherwise the condition giving rise to the overload would be of no particular consequence nor interest. Rather, the cautionary should have been the amplifier is not delivering its Maximum Available Power (once again, having raised this topic early on, it is curiously missing as a rhetorical observation). The dialectic seems to have promoted the subordinate thesis while the data in the observations have destroyed it.
4.The detuned state is an untested conjecture. Its inclusion adds nothing without both a rigorous examination and explaining the speculative correlation as causation.

73's
Richard Clark, KB7QHC

5537. Chapter 19A from "Reflections III" - Step 10 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:52:06 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <4utq54pd595cgr2qi3v1erctj23jdgibbo@4ax.com>
Source record: 24759

Step 10.
With the 17.98 + j8.77-ohm load still connected, the pi-network loading and tuning are now re-adjusted to again deliver all available power with drive level setting still left undisturbed. The readjustment of the plate tuning capacitor has increased the capacitive reactance in the pi-network by ï¿½8.77 ohms, canceling the +8.77 ohms of inductive reactance in the load, returning the system to resonance. The readjustment of the loading control capacitor has decreased the output capacitive reactance, thus reducing the output resistance from 50 to 17.98 ohms. Thus the network readjustments have decreased the output impedance from 50 +j0 to 17.98 ï¿½ j 8.77 ohms, the conjugate of the load impedance, 17.98 + j8.77 ohms. The readjustments have also returned the network input impedance ZL to 1400 + j0 ohms (again equal to RLP), have returned the original area of the RF window at the network input, and have returned the slope of the loadline to its original value. For verification of the 1400-ohm network input resistance after the readjustment, ZL was again measured using the method described in Step 2, and found it to have returned to 1400 + j0 ohms.

Points in response:
This step is fraught with leaps of faith substituting for sound, practical evidence.
1.This step consists of several steps. Rhetorically, what is the meaning of steps, to so much shift stylistically? This is not an isolated instance, so writing structure needs to be re-examined.
2.All Available Power, (a rhetorical shift from maximum) has not been established, much less shown. It is not denied that a greater power can be applied to the new load; but the actual amount of power is not reported (a reporting shift from earlier protocol).
3.The declaration of attaining a reactance of -j8.77 Ohms is unsubstantiated in reported measurements. This gives rise to the appearance of speculation serving the argument.
4.Likewise, the declaration of lowering the output (terminal) Z to 17.98 Ohms is a remarkably precise value without any measurement evidenced.
5.The verification measurement, a step of considerable substance, is rendered here as an footnote, clouding the earlier responses, 2 & 3 above, jarring against the lack of the actual measurements of -j8.77 Ohms and 17.98 Ohms. In a nutshell, the verification is shortchanged against the completeness of earlier measurements.
6.The adjustment of the plate load does not reveal a conjugation.

73's
Richard Clark, KB7QHC

5538. Chapter 19A from "Reflections III" - Steps 11 & 12 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:54:23 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <90uq54haiubnjmjh05e3fhtn4sa4o96hok@4ax.com>
Source record: 24760

Step. 11
Bird 43 power meter readings following the readjustment procedure now indicate 130w forward and 29.5w reflected, indicating 100.5w delivered to the mismatched load.

Points in response:
1. The cost of the variation in usage of the term Step now comes home to roost. This step is obviously simple reporting. However, it is reporting out of sequence, which is the purpose of offering Steps so that this can be avoided.
2. It also reveals the problems of precision offered where impedances are reported to 2 decimal places (exceeding the accuracy of equipment). Formerly, Maximum Available Power was explicitly defined (to one decimal place) as 100W, and now we find 100.5W applied to the newly matched load. The laws of precise reporting would suggest the earlier Maximum Available Power should have been specified at 100.0W (tenths of W precision); or consistent with its earlier 1% precision that this new reading should be offered as 101W (with appropriate promotion of the 0.5W).
3. I would point out that the Bird 43 Power Meter's accuracy is 5% of full scale and that to this point no specification has been offered as to what actual equipment is being used as there are seven possible plug-ins available (where only three would be sensibly chosen here). This gives rise to the author conferring upon the reviewer the power to choose for him. I will arbitrarily infer from the information provided that two plug-ins are used: 100W and 250W. The 100W would be selected for the first power reading offered in Step 1 as this would give the greatest accuracy to that cardinal point. The 250W element for the 130W reading in Step 11. I presume that the 100W element would be used for the reverse power readings, as that would be the greatest advantage; unless, of course, the 50W element was available (this is the hazard of incomplete reporting).
4. A 29.5W reading is both an interpolation (there are no half Watt gradations), and subject to error. The proper reporting would allow for the interpolation but cite it as 29.5W ï¿½5W (or nearly 17% of reading).
5. A more substantial ï¿½25W error inhabits the 130W reading due to the use of the 250W element. The proper reporting would allow for the interpolation but cite it as 130W ï¿½25W (or nearly 19% of reading).
Given that these are two, separate measurements, we have to render the delivered power as:
(155W .. 105W) + (-34.5W .. -24.5W)
where the optimistic combination of all inaccuracies offer a spread of delivered power:

120.5W .. 80.5W
This is a huge variation of ï¿½20W around what had been presumed to represent the Maximum Available Power of 100W (which, in itself could only have been reported as 95W .. 105W).
6. For the reader, there is a object lesson to be learned here in regard to RF power measurement accuracy where none is required (as I pointed out, the introduction of Maximum Available Power is an unnecessary elaboration to the subordinate thesis). That is, the greatest usage of the Bird (or any indicating instrument) would be found in returning the system to a cardinal reading point on its scale. This would collapse the nearly 20% error to less than one-tenth that value.... If it mattered at all (it doesn't).

5539. Chapter 19A from "Reflections III" - Step 13 response

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 21:55:39 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <i4uq54hirtlfcbblmv6k3j759q9tglla71@4ax.com>
Source record: 24761

Step 13.
It is thus evident that the amplifier has returned to delivering the original power, 100 watts into the previously mismatched complex-impedance load, now conjugately matched, the same as when it was delivering 100 watts into the 50-ohm non-reactive load. But the reflected power, 30.6 watts, remains in the coax, adding to the 100 watts delivered by the amplifier to establish the 130.6 watts of forward power, proving that it does not enter the amplifier to dissipate and heat the network or the tube.

Points in response:
1. The power accounting is wholly lacking in accuracy implications as previously noted.
2. That 30.6W remains in the coax has been through the intervention of the amplifier operator's tuning. The reflection of power from the original mismatch clearly impacted the dissipation of the finals without such intervention. Intervention was a necessity of preventing the untoward, catastrophic failure of the amplifier (in a general sense for all possible load reflection angles).
3. The 30.6W remaining in the coax is a function of tuning that cast the issues of dissipation out of the tube, and moved the line of dissipation towards the load (actually, into the tuning elements of the plate and the line itself). This is the whole raison d'etre of tuning the grid/plate or matching the load.

5541. RoomCap Antenna - last results

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-21 22:26:12 UTC
From: hb9abx <hb9abx@freesurf.ch>
Message-ID: <543f1cf2-df9d-4735-abcf-3b88a9eeade8@8g2000hse.googlegroups.com>
Source record: 24763

In September 2007 I conducted a short test between the Roomcap antenna and a large horizontal
Loop antenna. The result was unexpectedly good for the Roomcap.

To have certainty in this respect we planned a long test in which the following criterias applied:
- Installation of the test site, antennas, and cabling by communication specialists of the Army
- Both antennas connected through A/B switch to the same transceiver
- Several operator who log their communication results
- Always two operators: One operating the rig, the other logging the reports

The test was conducted on 40m in SSB under the callsign HB4FF.

This test took place on the 20th May 2008 in the military camp of the communication troops in Emmental.
They installed as comparison antenna a horizontal loop (86m wire (2 wavelength long), 12m above ground
on a free field, with smartuner SG-230 in the feedpoint).
The station was in a barrack next to the antenna. Two coaxes (RG214) were layed and led to the coax-switch
connected the the transceiver. The SWR of both antennas was 1:1.
The comparing antenna was a good one, as analysed by L.B.Cebik (W4RNL) here:
http://www.cebik.com/content/a10/wire/horloop.html
http://www.cebik.com/content/fdim/atl1.html
To access these links you need a passwort (free), which you may obtain here:
www.cebik.com/helpme.htm .

The installation and conduction of the test was supervised by a militay communication instructor.
I only had to drive with the Roomcap Antenna (1.5 m long radiator) to the parking place and connect my antenna
to the coax that was ready there. Connection was through two large current baluns who prevented that RF was
fed to the outside of the coax cable. Furthermore, the coax cable was laying on the ground.

Then, the test could begin. Operators were the two that came with me: Dave HB9KT and Benoit HB3YRX,
and two operators from HB4FF: Jürg HB9BFC and Rolf HB9CVB.

The test was conducted according to "HF antenna tests and comparisons", where in each contact the remote

operator was asked to observe the signal strength during several changeovers between the two antennas.
The antennas were just called "antenna 1" and "antenna 2", to prevent subjective influence. Important was
the signal strength difference und not the absolute value.
In this kind of comparison no calibration of the receiver is required, as we only needed to see the difference of
the signals, or the finding that both signals are equal.
The polarisation of the antennas does not play any role, as only sky wave contacts were accounted for. In these
waves the polarisation is changing permanently and unpredictable.

After 6 hours duration the test was ended, and evaluation of the logs could begin.
The result looks like this: (here is the log)

- In 57% of the contacts the Roomcap antenna received the better report.
- In 29% of the contacts both antennas produced equal signal strength.
- In 14% of the contacts the Loop antenna received the better report.

The largest difference in favor of the Roomcap was reported with 13 dB (abt 2 S points).
The largest difference in favor of the Loop was 6 dB (= 1 S point).

By calculating the arithmetic mean of the signal differences, one obtains a calculated advantage of 1.5 dB
in favor of the Roomcap antenna. This includes the fact, that the coax cable RG214 to the Loop had 2.7 dB more
attenuation (on 7 MHz) caused by the length difference, and that the connecting cable RG58 and the current baluns
had an attenuation of 0.7 dB. Accordingly, the Roomcap reports were reduced by 2 dB (= 1/3 S point).

Here follows the list of the stations who provided comparitive reports:

IK6ZNH, 2E1DHN, DJ6AL, DJ1JW, DL1HWT, DH7VK/p, 9A/DG2XO, DB9WJ, G3GBS, DL7FF, PA3FRD,
DL1BPK, DK0SC, DG1BM, HB9BWV/m, DL5XDL, G0GHK, F/PA0JWV, DJ9OI, OE2008SMC, DL1DXF.

HB9BWV/m reported a 30 dB stronger signal for the Roomcap. This report was excluded in the calculation, as
the station was in the ground wave at a distance of 25 Km, where the polarisation effect was responsible for
this high difference.

By switching between the two antennas during receiption, the same signal difference was noted as received
from the remote station. This shows that the antenna works in reciprocal way.

Conclusion:
This test proves clearly, that the efficiency of the Roomcap Antenna
equals that of large wire antennas,
and hereby confirms the results that I obtained during my own tests
during the last 3 years.
Each operator confirms the logged reports.

The physical explanation of this is, that generation of the EM waves
is done by the dynamic E field, as explained
in "Antennas and Physics". The dominating E field can be measured only
in the near field region of the antenna,
as in the far field a fixed relation between H and E field exists.
The far field does not allow determination how the
wave has been generated originally.

Many thanks to the above mentioned OMs for there voluntary, free
contribution in this antenna test.

Felix, HB9ABX

I have problems with your reference antenna though..
If they are trying to ensure efficiency from the reference
antenna, why use a multi wavelength loop fed with a tuner?
They would have been better off using a standard dipole, or
if a loop, a direct fed 1 wavelength loop for the band to be
used.
Also, this test does not prove that the efficiency of the "roomcap"
antenna equals that of large wire antennas.
All it proves it that at the time of the test and the path used,
that the roomcap antenna had a higher level of radiation at
that particular angle. This has nothing to do with efficiency.
If you really believe a 1.5 meter tall antenna is as efficient
as a 1/2 wave dipole fed with coax, I have some ocean front
property in AZ I'd like to show you.
I've had my mobile antenna outplay my 1/2 wave dipole at
certain times of the day and using certain "usually low"
angles. But I would never be so foolish as to suggest that
my mobile whip is just as efficient as my 1/2 wave dipole
at home.
Anyway, the testing is good to do, but this test has warts,
and I wouldn't place too much trust in it. I sure wouldn't go
so far as to claim any certain efficiency from the roomcap
antenna. I'm not too keen on the reference antenna you
used. It has warts too.. You are losing system efficiency
in the feed system using coax to a tuner.
And also the pattern of the multi wavelength loop would need
to be looked into. I'd almost bet money a 1/2 wave coax
fed dipole would have beat that loop in most all directions.
It would almost certainly have a higher system efficiency
by doing away with the tuner.
Anyway, I'm not too convinced.. :(

See Art, I don't just pick on you... Anyone with dubious
test results gets a comment from me...
I'm an equal opportunity heckler... :/

Ian,

I'll have to do some experimenting with the 300 Ohm feeder and see what happens. The End Fed on 40m is very poor indeed. I would say unusable like it is.

The End Fed wire at the moment is resonate on 2. 682 MHz.

The funny thing is that when I cut the wire to bring the End Fed to resonate on 80m, no matter how much wire I cut off it doesn't really move from the 2.682 MHz. I have tried this with and with out the ribbon feeder being in place and with coax connected direct and the braid connected to the earth rod.

What would cause this?

I have no problem using the Analyser with my mobile and centre fed dipoles.

The front is at the halfside where the gammamatch is attached. So you point the thing with its sides closest to the gammamatcher. 6 dB is a power increase of 4 times gentlemen ! The are available in three sizes. It stays on your mind, doesn't it ?

Felix , Since you are posting all this in a radio homebrew NG ,could you please give us all a free reference where to find the details of this miracle antenna , such that we can build one ourselves.

Frank GM0CSZ / KN6WH

oh, so the gamma match is doing the radiating and the loop is shielding it
from the 'back'. NOW that makes more sense.
```

As noted here you have to sign something and pay to get the construction
guide, you probably sign a non-disclosure agreement so you could be sued if
you published the plans:
http://home.datacomm.ch/hb9abx/kondition-e.htm

6db f/b can also mean a signal DECREASE to 1/4 of the 'front' signal
strength in the 'back' direction. it doesn't mean that there is gain in one
direction, simply that more power is going one direction than the other. i
can build a small loop and add a small vertical very close to it and
generate probably 20-30db f/b ratio, but it's signal compared to a dipole or
even a 1/4 wave vertical will suck... those antennas have been documented
for many years, but no one bothers using them for transmitting, only for
transmitter hunting as receive antennas.

>>dipoles.
>> 73 Andy

>adding a suitably cut wire counterpoise at +% for each band should
>certainly assist things .

I rather think that Andy can't add counterpoises. A decent earthing
system should work (although additional counterpoises certainly won't do
any harm).

Re the 2.682MHz resonance, this may be because the coax is completely mismatched at lots of frequencies, and what you're seeing this is more-or-less a spurious resonance of the coax itself. Do you still get it with the wire completely disconnected? Even with centre-fed dipoles, you often get some very unexpected resonances way off frequency (especially of you are doing a wideband frequency sweep of the return loss / SWR).

As I said previously, persuading an approximate halfwave endfed (which is what you have on 40m) to work with a coax feed is certainly not ideal, but you can usually get it to work fairly well (with all the provisos already discussed). My setup here is almost twice the size of what you have, so the wire feed impedance will be low on 160m and I high on 80m and 40m. 80m (corresponding to your 40m) is certainly lively enough. On 40m, the performance does not seem to be unduly poor compared with the signal reports swapped between others on the band.

So, Andy, I simply don't know why your 40m is so poor. Have you tried (temporarily) reducing the length to around 33 feet, so that it is a quarterwave on 40m? This should give a reasonable match for your coax (at least, nothing you can't tune out back in the shack). If this is more lively than the 64 feet, maybe you can try two wires in parallel. This can be discussed later if the 33 feet shows promise. If a multiband (and possibly compromise) aerial doesn't work well, it's a good idea to try something simple which you know SHOULD work. The problem may lie elsewhere.

Finally, can I ask you to follow the standard practice of bottom posting!
Cheers...

Indeed ,he has tried that for the past 2-3 years via the Packet Radio
System . Not very much in the spirit of amateur radio , whereas for
most of his tests Felix uses radio amateurs trying to prove the
effectiveness of his 'invention'.

mister. First you couldn't read the front-to-back ratio diagram. And now this stupid remark.
Better you stay away here with your lowlevel non constructive shill-mentality !

If you understanding is so little, don't bother us with it. Go to your mother or a shrink. Anything but go !

now that is what i expect from someone who is trying to defend their exagerated claims... just go away, don't try to explain why or how you measured a f/b on a loop... you obviously observed something you can't explain so you now assert that anyone who doubts you must be crazy or doesn't understand. I understand snake oil claims when i see them. And yes, i do know that many people use loops for transmitting, i also know that many people who have their choice of antenna don't bother with them because they don't perform as well as other designs... but if all you can do is a small loop on your property, then its better than nothing.

of course he can , he has a run of crap coax so when he replaces it
with some rg213 adding some multi strand suitably trimmed one be a
burden from the far coax connection back
A decent earthing

Oh, I think under the circumstances, that RG-58 isn't all that bad. May not have the lowest losses possible, but certainly not complete 'crap'. Replacing it with something 'better' is certainly an option, but not the first one I'd try.
Options.
Try all that you can think of and see what happens. If things are 'better' on one particular band doing it 'this' way, then I think I'd note that when using that particular band. Repeat for the other bands. Lots of work? Sure, but if it works, it works. Finding one antenna that does it all is almost impossible. Too many variables depending on each individual installation. But, if you get 'close', that's probably as good as you can expect, depending on the circumstances. Having the absolute 'best' antenna in the world is certainly nice! It isn't absolutely necessary. Everyone goes through this same sort of thingy. The results differ, but so do the circumstances.
Good luck.

"Why don't every American have this aerial ? It is beyond Big!"
Yep, big... and expensive. Probably two good reasons why not all of us have one. Never used one so can't say if it's any good or not. I have used loops (big ones) made of wire and I like the results. A single loop, all by it's self, has no appreciable directivity. Certainly possible with another 'element', or something near it, but not just by it's self. Sorry 'bout that.

5566. Rebuttal to Richard Clark's comments on my Chapter 19A

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-22 16:33:41 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <_9v7k.6$b%3.2@newsfe05.lga>
Source record: 24788

RICHARD:

I've known you for a long time to be tough but fair. I've envied your depth of knowledge in many areas of expertise. Which is why I entrusted you and others on this thread with my Chapter 19A for an honest peer review. I expected to receive a fair review from you that would fare well in proving my paper correct for those who don't yet understand, or don't believe the principles involved.

However, instead of receiving a fair critique of my paper you trashed it with an axe. Every criticism you made was not only negative, but clearly false. If I didn't know you better I would conclude from your comments that you don't have a clue concerning the operation of RF amplifiers.

Since you chose to denigrate my writing instead of giving it a fair critique, why did you broadcast it on the news group instead of discussing your position with me privately? Since you have broadcast it I have no choice but to defend my position by rebutting each and every one of your false statements on this thread for all to see.

Thus I'm repeating your comments with my responses to them to set the record straight.

Richard says:

Hi All,

This is simply a quick overview from the separate threads that will follow, each thread devoted to only one Step in the progression of measurements Steps offered by Walt Maxwell in his upcoming release of "Reflections III," Chapter 19A in particular.

I have been working off of three revisions of this work, and some quotes may not be accurate. I will leave reconciliation of those to others as this has been a long and exhaustive examination, and I don't perceive any substantive issues shifted along the way. Not all steps will be critiqued as not all contain response beyond my noting they contained simple reports of fact that did not merit challenging. A full article length version containing all discussion of this will be available.

The discussion threads follow immediately.

Walt says:

The numbered steps are quotes from Chapter 19A

Step 1.
Using a Kenwood TS-830S transceiver as the RF source, the tuning and

loading of the pi-network are adjusted to deliver all the available power into a 50 + j0-ohm load with the grid drive adjusted to deliver the maximum of 100 watts at 4 MHz, thus establishing the area of the RF power window at the input of the pi-network, resistance RLP at the plate, and the slope of the load line. The output source resistance of the amplifier in this condition will later be shown to be 50 ohms. In this condition the DC plate voltage is 800 v and plate current is 260 ma. DC input power is therefore 800 x 0.26 a = 208 w. Readings on the Bird 43 wattmeter indicate 100 watts forward and zero watts reflected. (100 watts is the maximum RF output power available at this drive level.) From here on the grid drive is left undisturbed, and the pi-network controls are left undisturbed until Step 10.

Richard says:
There are several points in response here:
1.The load specification (50 + j0-ohm) is for full output power, not some portion of it. This is a minor point.

Walt says: This is NOT a minor point. The output power at 100 watts was specified as the reference power, not the full output power the xmtr could produce.

2.Maximum power from a TS-830S can be as high as 120W, could be lower depending on finals' service life. This is a minor point.

Walt says: This is also NOT a minor point. The TS-830S used for the measurements is capable of producing more than 130 watts, but 100 watts was used to assure stability that could be compromised if running the xmtr at its full output.

3.Rated typical Plate Current for the 6146B is 220mA. Running more at higher voltage (typical is 750V) to obtain less power sounds like the amp is being strained to produce 100W.

Walt says: Rated plate current is irrelevant here. The plate voltage in this xmtr is inherently 800v when the plate current is 260 ma. Running more than 750v to obtain less power is an absurd and unwarranted statement. The amp was NOT being strained to produce 100 w, because its full output exceeds 130 w.

4."Available Power" is 208W. Efficiency and other considerations certainly lower this, but it would appear that efficiency has been red-lined at 48% by this step's assertions. The red-line at 48% efficiency may reveal the aforementioned strain.

Walt says: Available power is NOT 208w. 208w is the DC input power. The true available power was 100w because the grid drive was set to allow only 100w to be delivered with loading adjusted to deliver all the available power at that drive level. This condition is clearly stated in Step 1.

Step 2.
The amplifier is now powered down and the load resistance RL is measured across the input terminals of the resonant pi-network tank circuit (from plate to ground) with an HP-4815 Vector Impedance Meter. The resistance is found to be approximately 1400 ohms. Because the

amplifier was adjusted to deliver the maximum available power of 100 watts prior to the resistance measurement, resistance RLP looking into the plate (upstream from the network terminals) is also approximately 1400 ohms. Accordingly, a non-reactive 1400-ohm resistor is now connected across the input terminals of the pi-network tank circuit and source resistance ROS is measured looking rearward into the output terminals of the network. Resistance ROS was found to be 50 ohms.

Richard says:
Points in response:
1.This is actually two steps: one measurement made from the plate looking towards the load; one measurement made from the output jack looking towards plate.
2.The measurement at the plate without a powered tube unloads the Q of the plate tuning. Does this unloaded Q present a false reading of the transformed load resistance?

Walt says: No, it does not.

Richard continues:
3.The load line with 800 v / 0.26 a / 2 = 1539 Ohms.

Walt says: The above statement is false. The load line is not determined by the DC components-it is determined by the AC components using the Chaffee analysis procedure.

Richard continues:

4."Maximum Available Power" has not been established, only arrived at by inference. It could be more, it could be less. Being less is unlikely given the subsequent demonstrated power delivered to the load being 100W; but it is suspect that exactly 100W is all that could be obtained. The point, however, is that such attention to "Available Power" is an unnecessary elaboration to the point of taking these steps.

Walt says: Maximum available power was NOT arrived at by inference. It WAS established in Step 1 by setting the grid drive so that maximum available power with that setting was 100w. Richard's statement that attention to available power is an unnecessary elaboration is totally false, because a constant available power is required as a reference for all the measurements. It is clearly stated in one of my earlier statements that the xmtr was capable of delivering more than 130w.

Richard continues:

5.The measurement at the output towards the plate similarly unloads the plate tuning Q when the 50 Ohms is removed to make the measurement. Does this unloaded Q present a false reading of the transformed plate resistance?

Walt says: No, it does not. This method is standard procedure in making initial adjustments of the tank circuit of newly manufactured xmtrs prior to applying

the plate voltage.

Richard continues:
6.The measurements made in both directions confirm the capacity of an unloaded circuit to perform the transformations in a symmetric fashion (a good test), but you have not tested if the issue of loaded Q is a factor or not. If you were to replace the 1400 Ohm resistor at the plate tuning input (at the plate connection) with a 1000 Ohm resistor, would the 50 Ohms follow that shift? By how much?

Walt says: Yes it would. If this pi-network is adjusted such that a 1400-ohm resistor at the plate connection would yield 50 ohms at the output of the network a 1000-ohm resistor replacing the 1400-ohm, the resistance appearing at the output would be 35.71 ohms

Step 7.
Due to the 2.88:1 mismatch at the load, neglecting network losses and the small change in plate current resulting from the mismatch, approximately the same mismatch appears between RLP and ZL at the input of the pi-network. Consequently, the change in load impedance changed the network input resistance RL from 1400 ohms to complex ZL ~ 800 - j1000 ohms, measured with the Vector Impedance Meter using the method described in Step 2. To verify the impedance measurement of ZL the phase delay of the network was measured using an HP-8405 Vector Voltmeter and found to be 127°. Using this value of phase delay the input impedance ZL was calculated using two different methods; one yielding 792 - j1003 ohms, the other yielding 794.6 - j961.3 ohms, thus verifying the accuracy of the measurement. However, because grid voltage EC, grid drive Eg, and plate voltage EB are left unchanged, resistance RLP at the plate has remained at approximately 1400 ohms, leaving a mismatch between RLP and ZL at the input of the pi-network. As stated above, this value of ZL yields the substantially the same mismatch to plate resistance RLP as that between the output impedance of the pi-network and the 17.98 + j8.77-ohm load, i.e., 2.88:1. This mismatch at the network input results in less power delivered into the network, and thus to the load, a decrease in the area of the RF window at the network input, and a change in the slope of the loadline. (It must be remembered that the input and output mismatches contribute only to mismatch loss, which does not result in power delivered and then lost somewhere in dissipation. As we will see in Step 8, the mismatch at the input of the pi-network results only in a reduced delivery of source power proportional to the degree of mismatch.)

Richard says:
Points in response:
1.We enter into a key remark in the first sentence: neglecting network losses and the small change in plate current resulting from the mismatch. By this statement the subordinate thesis being offered: output source resistance of the RF power amplifier is non-dissipative is wholly invalidated.

Walt says: The last sentence above is totally false. The increase in plate current due to the mismatch causing the pi-network to be detuned does cause the increase in plate dissipation, but plate dissipation occurs only in the cathode-to-plate resistance, which is totally irrelevant to the output source resistance, which IS non-dissipative.

Richard says:

The observation that the plate current changes
(and presumably plate voltage has not, unconfirmed in the protocol)

Walt says: Not so. While the plate current increased to 290 ma. The voltage decreased to 760v, clearly stated in Step 9.

Richard continues:
through the agency of mismatch must necessarily admit that the plate resistance has also changed if only because it has been explicitly admitted to through the dismissed current change.
2.To whatever degree (as dictated by the phase of the mismatch), plate dissipation must also change. This is the common experience of literally thousands of Amateur radio operators and has been commented upon and reported for generations when through the unfortunate aspect of phase, it becomes a destructive dissipation.

Walt says: Of course the plate dissipation changed with the increase in plate current caused by the detuning of the network. But as said before, this plate dissipation is irrelevant to the output source resistance.

Richard continues:

Such reports often
attain dramatic legendary status, if only for the afflicted amplifier owner (who may enjoy comedic celebrity among his peers).
3.Moving on to subsequent sentences, the reported values of complex load resistance (792 - j1003 Ohms) seen from the plate looking through tuning towards the new, mismatched load confirms that the plate resistance must be impacted. If, as reported, the plate resistance remains at 1400 Ohms, then there is a mismatch which is admitted to in the text of the original. The final argument is based upon mismatch loss, which from the perspective of the load, is that amount of power not seen, but not lost by dissipation. That much is true from the perspective of the load. The same would be true if we replaced the plate tuning with a large resistor which would also reduce power to the load, so such an appeal has nothing to do with the argument of the subordinate thesis: output source resistance of the RF power amplifier is non-dissipative. The nature of this particular plate mismatch affirms the current indication, and rejects the conclusion of non-dissipation (which is characteristically, and artificially constrained to being exothermic when through phasing it could as easily be endothermic).

Walt says: Richard is totally off base in attempting to correlate the plate dissipation with the output source resistance at the output terminals of the network. They are totally unrelated.

Richard says:

4.A more careful protocol would allow for phase by lengthening the 13.5° length of coax to 103.5° (or more but well less than 180°) and carefully noting the new plate current. In fact, other lengths should be used to draw a more rigorous correlation.

Walt says: Richard ignores the fact stated later in my paper that I have already made measurements with several different lengths of coax that also verify the measurements reported here to be correct.

Step 8.
Readings on a Bird 43 power meter now indicate 95w forward and 20w reflected, meaning only 75 watts are now delivered by the source and absorbed in the mismatched load. The 20w reflected power remains in the coax, and adds to the 75 watts delivered by the source to establish the total forward power of 95w.

Richard continues:
Point in response:
The Bird 43 indications only reveal mismatch loss (unstated as 5W if we are to return to the concept of Available Power, which as a rhetorical point has been uncharacteristically discarded) which is only tangentially related to the subordinate thesis: output source resistance of the RF power amplifier is non-dissipative. Step 7 is sufficient to illustrate the thesis.

Walt says: The above paragraph is totally without merit, and only serves to confuse the reader.

Step 9.
We now compare the measured power delivered with the calculated power, using the power transmission coefficient, 1 - ?2. The calculated power delivered is: 100w ° (1 - ?2) = 76.6w, compared to the 75w indicated by the Bird wattmeter. However, because the new load impedance is less than the original 50 ohms, and also reactive, the amplifier is now overloaded and the pi-network is detuned from resonance. Consequently, the plate current has increased from 260 to 290 ma, plate voltage has dropped to 760 v, and DC input power has increased from 208 w to 220.4 w.

Richard says:
Points in response:
1.This is a surprising departure from reporting in the progression of the protocol. We now find current and voltage reports where formerly they were either dismissed or neglected. However, we will take these as they are reported here.

Walt says: Voltage and current were NOT dismissed or neglected. They were presented in Step 9 as the natural progression in explaining the test procedure.

Richard continues:

2.It appears that the calculated power and the reported power agree,
this is not directly expressed, but neither these remarks are not
stated as being in conflict. Given the editorialization that inhabits
the protocol in general, these remarks are remarkably dry and
unconnected.
3.Following, with the editorial comment that the amplifier is now
overloaded, the connotation is necessarily a rejection of the thesis:
output source resistance of the RF power amplifier is non-dissipative;
otherwise the condition giving rise to the overload would be of no
particular consequence nor interest.

Walt says: The amplifier was overloaded because the load impedance was less than that with the reference load of 50 + j0 ohms. Richard still fails to understand that the dissipation in the cathode-to-plate resistance is totally unrelated to the output source resistance, because the output source resistance is determined only by the voltage-current ratio appearing at the output terminals of the network.

Richard continues:

Rather, the cautionary should
have been the amplifier is not delivering its Maximum Available Power
(once again, having raised this topic early on, it is curiously
missing as a rhetorical observation). The dialectic seems to have
promoted the subordinate thesis while the data in the observations
have destroyed it.

Walt says: The last statement above is totally false.

4.The detuned state is an untested conjecture. Its inclusion adds
nothing without both a rigorous examination and explaining the
speculative correlation as causation.

Walt says: There is no speculation or untested conjecture here. The fact that the network was detuned by the mismatched load containing reactance is proven by the fact that retuning the network to resonance was by adjusting it to obtain the plate-current dip.

Step 10.
With the 17.98 + j8.77-ohm load still connected, the pi-network
loading and tuning are now re-adjusted to again deliver all available
power with drive level setting still left undisturbed. The
readjustment of the plate tuning capacitor has increased the
capacitive reactance in the pi-network by -8.77 ohms, canceling the
+8.77 ohms of inductive reactance in the load, returning the system to
resonance. The readjustment of the loading control capacitor has
decreased the output capacitive reactance, thus reducing the output
resistance from 50 to 17.98 ohms. Thus the network readjustments have
decreased the output impedance from 50 +j0 to 17.98 - j 8.77 ohms, the
conjugate of the load impedance, 17.98 + j8.77 ohms. The readjustments
have also returned the network input impedance ZL to 1400 + j0 ohms
(again equal to RLP), have returned the original area of the RF window
at the network input, and have returned the slope of the loadline to

its original value. For verification of the 1400-ohm network input resistance after the readjustment, ZL was again measured using the method described in Step 2, and found it to have returned to 1400 + j0 ohms.

Richard continues:
Points in response:
This step is fraught with leaps of faith substituting for sound, practical evidence.
1.This step consists of several steps. Rhetorically, what is the meaning of steps, to so much shift stylistically? This is not an isolated instance, so writing structure needs to be re-examined.
2.All Available Power, (a rhetorical shift from maximum) has not been established, much less shown. It is not denied that a greater power can be applied to the new load; but the actual amount of power is not reported (a reporting shift from earlier protocol).

Walt says: All the available power WAS ESTABLISHED AND SHOWN IN STEP 10, quoting: "With the 17.98 + j8.77-ohm load still connected, the pi-network loading and tuning are now re-adjusted to again deliver all available power with drive level setting still left undisturbed." All available power was initially set to be 100w determined by the drive level which was left undisturbed.

Richard continues:

3.The declaration of attaining a reactance of -j8.77 Ohms is unsubstantiated in reported measurements. This gives rise to the appearance of speculation serving the argument.

Walt says: No speculation, and the -j8.77 ohms is not unsubstantiated, because that reactance introduced into the network resulted in the network becoming resonant in that it canceled the +j8.77 ohms appearing in the load. No additional measurement is required to determine the existence of the -j8.77 ohms.

Richard continues:
4.Likewise, the declaration of lowering the output (terminal) Z to 17.98 Ohms is a remarkably precise value without any measurement evidenced.

Walt says: All available power is delivered when the load resistance is equal to the source resistance. The load resistance was 17.98 ohms. Because all available power was delivered into 17.98 ohms the output resistance is inherently 17.98 ohms.

Richard continues:
5.The verification measurement, a step of considerable substance, is rendered here as an footnote, clouding the earlier responses, 2 & 3 above, jarring against the lack of the actual measurements of -j8.77 Ohms and 17.98 Ohms. In a nutshell, the verification is shortchanged against the completeness of earlier measurements.

Walt says: Richard is really clutching at straws here in his attempt to discredit my measurements.

Richard continues:

6.The adjustment of the plate load does not reveal a conjugation.

Walt says: With the plate current again dipped at 206ma. now at resonance with the initially mismatched load, the same plate current obtained at resonance with the 50-ohm load, proves the match now existing at the network output is a conjugate match.

Step. 11
Bird 43 power meter readings following the readjustment procedure now indicate 130w forward and 29.5w reflected, indicating 100.5w delivered to the mismatched load.

Richard continues:
Points in response:
1. The cost of the variation in usage of the term Step now comes home to roost. This step is obviously simple reporting. However, it is reporting out of sequence, which is the purpose of offering Steps so that this can be avoided.
2. It also reveals the problems of precision offered where impedances are reported to 2 decimal places (exceeding the accuracy of equipment). Formerly, Maximum Available Power was explicitly defined (to one decimal place) as 100W, and now we find 100.5W applied to the newly matched load. The laws of precise reporting would suggest the earlier Maximum Available Power should have been specified at 100.0W (tenths of W precision); or consistent with its earlier 1% precision that this new reading should be offered as 101W (with appropriate promotion of the 0.5W).

Walt says: Picky picky picky.

Richard continues:

3. I would point out that the Bird 43 Power Meter's accuracy is 5% of full scale and that to this point no specification has been offered as to what actual equipment is being used as there are seven possible plug-ins available (where only three would be sensibly chosen here). This gives rise to the author conferring upon the reviewer the power to choose for him. I will arbitrarily infer from the information provided that two plug-ins are used: 100W and 250W. The 100W would be selected for the first power reading offered in Step 1 as this would give the greatest accuracy to that cardinal point. The 250W element for the 130W reading in Step 11. I presume that the 100W element would be used for the reverse power readings, as that would be the greatest advantage; unless, of course, the 50W element was available (this is the hazard of incomplete reporting).
4. A 29.5W reading is both an interpolation (there are no half Watt gradations), and subject to error. The proper reporting would allow for the interpolation but cite it as 29.5W ±5W (or nearly 17% of

reading).
5. A more substantial ±25W error inhabits the 130W reading due to the use of the 250W element. The proper reporting would allow for the interpolation but cite it as 130W ±25W (or nearly 19% of reading).
Given that these are two, separate measurements, we have to render the delivered power as:
(155W .. 105W) + (-34.5W .. -24.5W)
where the optimistic combination of all inaccuracies offer a spread of delivered power:
120.5W .. 80.5W
This is a huge variation of ±20W around what had been presumed to represent the Maximum Available Power of 100W (which, in itself could only have been reported as 95W .. 105W).
6. For the reader, there is a object lesson to be learned here in regard to RF power measurement accuracy where none is required (as I pointed out, the introduction of Maximum Available Power is an unnecessary elaboration to the subordinate thesis). That is, the greatest usage of the Bird (or any indicating instrument) would be found in returning the system to a cardinal reading point on its scale. This would collapse the nearly 20% error to less than one-tenth that value.... If it mattered at all (it doesn't).

Walt says: In the above unnecessary discourse Richard is only showing off his expertise as a metrologist.

Step 13.
It is thus evident that the amplifier has returned to delivering the original power, 100 watts into the previously mismatched complex-impedance load, now conjugately matched, the same as when it was delivering 100 watts into the 50-ohm non-reactive load. But the reflected power, 30.6 watts, remains in the coax, adding to the 100 watts delivered by the amplifier to establish the 130.6 watts of forward power, proving that it does not enter the amplifier to dissipate and heat the network or the tube.

Richard continues:
Points in response:
1. The power accounting is wholly lacking in accuracy implications as previously noted.

Walt says: Totally false. The only inaccuracies are in the measurement errors inherent in the measurement equipment that come with the territory. The large deviations in the precisions Richard alludes to are unrealistic.

Richard continues:
2. That 30.6W remains in the coax has been through the intervention of the amplifier operator's tuning.

Walt says: Totally false. The 30.6w remains in the coax because the reflected power was totally re-reflected because the non-dissipative source resistance reflected it. If the source resistance had been dissipative the reflected power would have been only 25w, not 30.6 watts, and the 25w would have been absorbed

in the source, which it was not.

Richard continues:

The reflection of power from the
original mismatch clearly impacted the dissipation of the finals
without such intervention. Intervention was a necessity of preventing
the untoward, catastrophic failure of the amplifier (in a general
sense for all possible load reflection angles).
3. The 30.6W remaining in the coax is a function of tuning that cast
the issues of dissipation out of the tube, and moved the line of
dissipation towards the load (actually, into the tuning elements of
the plate and the line itself). This is the whole raison d'etre of
tuning the grid/plate or matching the load.

Walt says: Although the reflected power caused the mismatch appearing at the input of the 13 line, the reflection of power itself did not affect the dissipation of the amp, because the reflected power never entered the network. It was simply the reactance in the load that detuned the network that increased the dissipation, as would be expected when the network is detuned from resonance.

I hope my responses have sufficiently explained why Richard's criticism is so
outrageously incorrect. I have no clue as to his motivation for discrediting my
writing to this extent, because it is totally unwarranted.

Walt, W2DU

> Walt, W2DU

Walter, what you give out you eventually receive and the same goes for
Richard.
Oft times you level charges against others for the fun oif it and then
get annoyed if others do likewise.
You and Richard are well known with respect to attempts to slaughter
other peoples thoughts and ideas
and get indignant when retaliation occurrs or when others follow on in
the game.Both of you will never
be in a position to
declare all you thboughts are correct and most of those who oppose you
are not simply because you both over estimate your abilities and
position amoung your followers
You both started it so it is reasonable that you both would eventually
turn upon each other.
Obviously both you and your followers have given up trying to
suppress Cecil's thinking. Good for him.

I've have just connected the Analyser at the feed point on the End fed wire.
The frequency is now at 2.898 MHz without coax being in line. I have just
tried
to shorten the Antenna again to bring the frequency closer to the 80m band,
but
it will not adjust from this frequency.

What's confusing me is that the End fed wire should be longer than a 1/4
wave on 80 and the frequency that it ended up on, that is now 2.898 would be
about right for the length. So why won't that frequency change when I start
trimming the wire down in size?

It just isn't making any sense to me. The resonant frequency surely should change with the altered length.

73 Andy

Could all of you experts who can count the angels on the head of a pin but obviously cannot read English, please take this to a relevant newsgroup? This is not an antenna issue, and doesn't belong anywhere in the same zip code with rec.radio.amateur. ANTENNA.

If your egos just absolutely demand publication, perhaps a new newsgroup with the name "dummy load" would suffice. and any of you could start it. Personally, I'll be very careful to avoid it.

Ummmm...
Obviously something is wrong. It looks like your analyser is simply
telling lies. Could it have a spurious resonance at this frequency?
>
>What's confusing me is that the End fed wire should be longer than a 1/4

A quarterwave on 80m is around 66 feet. Your 63 feet is actually a bit
on the short side. Being only 20 feet up may pull the resonance a bit
lower, but I doubt is could be anywhere as low as 2.898MHz.

>So why won't that frequency change when I start
>trimming the wire down in size?
>It just isn't making any sense to me. The resonant frequency surely should

>
If shortening the aerial doesn't change the frequency, I don't think
your analyser is measuring the aerial. This is indeed a puzzle. As I
suggested before, you could go from the sublime to the ridiculous, and
try something like 33 feet, which should resonate at around 7MHz. If it
sticks at 2.898MHz, something is seriously amiss.

Sorry if the posts offended you, Harold, but I'm flabbergasted that Richard had the gall to post his denigration of my paper in the newsgroup. With common sense he should have known to send his comments to me, not to broadcast them. I felt I had no choice but to put my rebuttal in the same place to defend myself from from his unwarrented comments.

Walt, W2DU

I'd simply like to know -
1 - Who the fuck are you?
2 - What the fuck is chapter 19A?
3 - Why the fuck have you wasted so much
space on this antenna newsgroup with your
post asking for reviews and then getting
your panties wadded when someone "denigrates"
your stupid ass paper?

Fuck you and your fucking chapters.

Or you are:

A) A lier in addition to being a babbling arm waver.

B) Too clueless to know what "plonk" means or how to actually do it.

C) All of the above.

Hi Walt,

I posted the Steps, contrary to the typical slap-dash past, as then
they've been ignored, speculated, and "interpreted" without direct
quotation for 130 postings from many authors before mine. The
material of Chapter 19A was thus in the public debate by invitation
long before I dipped my bucket into this well.

I posted each step individually to create separate, one topic threads
and to reduce the reading load of one 600 line submission.

Any issue of my not having backfilled missing knowledge to the Steps
is a comment on the Steps' original style, not the chapter's original
content. I am responsible for neither and I am doing the job of
editor revealing faults of ordering, and wholes in continuity. If
this is perceived as a personal slight, I am sorry.

Comparing my 9 posts as poison to the 130 others' treacle informs everyone that I have at least attended specific technical points that can be identified and correlated. In other words, I purposely and at some great effort and time have taken personal responsibility for explicit statements.

In any future correspondence, I will only respond to technical issues within those threads to maintain continuity of discussion.

Walter, I can delete posts as well as the next guy, the point is, I shouldn't need to. You started the whole thing by giving Cecil the push. You, he, and several other off topic posters have just close to ruined a newsgroup that used to be a useful source of information concerning antennas. Then there's always the rebuttal to the rebuttal ad nausium. I know that you are as convinced as Bruene is of the sanctity of your convictions, you should realize, that the vast majority of the rest of us don't really care which of you are right. We've successfully managed to load our rigs, work the world, and obtain some happiness without the knowledge you insist on imparting to us. Please don't common sense Richard. With common sense, you wouldn't have sent 19A to Cecil in the first place but your ego got in the way.

I'll not entertain the group with any more of this, I would hope that you take my earlier post to heart and get off the newsgroup unless you have something to post that contributes to the antenna sciences.

W4ZCB

Walter, when I placed my page unwinantennas.com/ on this antenna
discussion group
you and Richard had the gall to attack me and my work just for the fun
of destruction.
My page which is on antennas by the way shows the path why antennas
can be any
shape ,size or configuration including variable elevation as long as
it is in equilibrium.
You and Richard took on the quest to crush the idea before it was
discussed fully while Richard denied
that the Gaussin progression could not be equal to Maxwells law., A
position he reversed himself on
a few months later without apology after discussion was succesfully
dissed. You as a expert book author chose gthe path of insults without
one iota of professional comment.
Shame on both of you. This group is for the discussion of antennas and
when I brought forward the
equilibrium matter forward I beat you to the punch by providing the
mathematical aproach first.
Neither of you discussed seriously what I proferred so neither of you
could find fault with it and Richard was particarly vicious
with his attacks and not once finding an error. You both destroyed the
idea of antenna discussion and debate on this newsgroup
because you both over estimate your own abilities while taking the
pagth of destruction. I worked hard at what I did and then shared it
with my fellow amateurs so all could enjoy. You Walt and Richard
deserve each other, as they say,what you sow so may you reap!. Some
day hams will be allowed to discuss or debate antenna matters without
fear of attack from you and your followers who provide nothing of
technical content to the discussion searching only for a "me too"
aproach. Maybe now that both of you have shown your true colours or
GALL as you call it other true hams will come back and discuss
antennas without being pushed aside. Wiered how you both take offense
of a tactic that you have practiced for years upon others with some
relish and now complain of the tone of debate or critism that do not

match your own position of chief adjudicater on the subject of
radiation.

MFJ Analyser ????

Isolate the transmission line (coax) from the antenna, ie; UGLY BALUN, Line Isolator

analyser may have copted a nose full of RF from the braid of feedline, with such a mismatch

should build resonant antennas first, before inserting giant matcher, just to see how much of your RF is dissipated in the match box. TX and RX

I haven't had time to try a 33" End fed to see if it would tune on 40m .But I did have time to connect a temp 60 feet of wire from the top of the ribbon feeder on the braid side to make a close 63 feet centre fed dipole fed with 300 Ohm feeder and the antenna resonates at 3.780 MHz with a 1.1:1 and the AT1KP backs this reading up. I haven't tried to lengthen or shorten the antenna yet. To see if it changes resonance, but I will do tomorrow.

It can't stay like that unfortunately.

So either my Analyser doesn't like to read End Fed antennas or there something else causing the funny readings. If the Analyser senses the change in frequency tomorrow when I start lengthening the antenna then it must be working OK or there is a fault with it and it can't read End Fed wires correctly. Is this even possible considering its reading everything else correct.

What do you think?

Unless I mis-read something, Andy says that he tried the analyser
directly on the antenna (at the antenna feedpoint) - so no coax was
involved in this particular test.

He seems to get a resonance at 2.898MHz, regardless of the length of the
antenna. Could this be because there is a strong (and permanent) RF
signal which is being picked up on the antenna, and is confusing the
analyser?

I am sorry, I just didn't know who I was dealing with when this began
with you ...

You are the BIGGEST idiot I have ever seen, good going dude ... you make
quite a coffee table conversation piece around here.

Regards,
JS

Andy, you've gone back to top posting, and this makes it very difficult
to follow the discussion. In newsgroups (unlike emails), you should
really post at the bottom. This is the established convention.

Anyway, it's interesting what you have found out with the dipole
configuration. Presumably, you still have the coax braid and one side of
300 ohm feeder earthed. If so, I would not have expected there to be
quite such a dramatic change of resonance. However, if your earth rods
are totally ineffective (or you have disconnected the earth), you might
expect things to change a lot when you add 'the other half of the
dipole'. If you actually have room to put up an appx 60 foot + 60 foot
dipole, why not consider a G5RV (which, I believe, you have already
tried) or a W3DZZ trap dipole? This would get rid of your earthing
problems.

If you did a google on the author's name and perhaps the word "reflections",
you might get the answers to your questions. You might also discover that
it is related to antenna systems.

Yup. That is correct. this is the third time he has published this
book in the hope of finally getting it right
but apparently it is discredited before publishing by the antenna
group! expert

Art, I wish you'd get your facts straight before you post. To set the record straight the 1st edition of Reflections sold out at 10,000 copies, the 2nd edition at 3,000 copies, while the 3rd edition hasn't been published yet. Nothing about anything pertaining to Reflections has been discredited. Who told you it has been? If you'd like to look at a few of the chapters go to my web page at www.w2du.com.

Walt

I don't care who the author thinks he is.

But if he posts to a public forum, asking for critique,
then getting pissed because someone
"had the gall to post his denigration of my paper"
then I guess he's just not as important as he,
and you, think he is.

Yes , could be a product of a Broadcast station ?
ok on the NO COAX, unless damage has been done.

tricky, will keep you off the streets, and out of the pubs Andy,
or perhaps in the pubs full as a boot if you do not get some answers soon
good luck

Do you go through a lot of keyboards sitting there grinning and drooling
on them?

You shouldn't be using big words whose meaning you don't know, like
"troll".

I have your book and I don't think much of it. With respect to facts
Richard lied about the mathematical connection between Gauss and
Maxwell. Most of you believed him without checking the facts and I was
dissed. Then a doctor Davis came aboard and showed you where you were
wrong but now everybody was committed and dissed him also. Yes, I was

discredited on a lie , which he admitted to after I was victimised by all. Now he has discredited your book and you on the basis of what you call" lies". I got no apologies and neither did Dr Davis
and the lie you were part of goes on to this day. You ask for facts you got them and they are still in the archives. You are calling the kettle black. Get back to antennas and stop promoting yourself and your third book which you claim is now right.You at least got some reasons as to why your postings were dissed, for my troubles I got nothing.It is evident that the majority of this newsgro0up do not like the move under way to change the subject of antennas so why not try to get along with your fellow posters
or move on?

By the way Walt you never came forward with the math to prove me wrong preffering a hatchet job instead of doing the math. You never apologised either
on continuing what I am sure you knew was a lie because of your continual position
of being superior in mathematics. The position you took makes you an accessory in the lie
because you knew it was a lie. You and your book have been dissed even if you can prove that Richard lied again
but after the fact it is difficult to put things right. Instead of telling me to read your page why not read
unwinantennas,com/ and the antenna group archives plus your own history on postings to refresh yourself on the "facts" that you wish for.
If you wish to make a rebuttal on the Gauss/Maxwell question be my guest and point out why you disagreed even in the face of Richard stating that he lied or are you committed to deeply now to reverse course instead of revealing the truth because it may hurt?

Art, I'm not a constant participant on the newsgroup, I've missed it a lot of the time. So I don't know a Dr. Davis, nor do I know anything about a lie. And what position do you think I took that would make me an accessory to a lie that I know nothing about? I read quite some time ago that there was a discussion concerning Gauss and Maxwell, but I didn't get into it, so I don't even know who were discussing them. So how could I be in a position to make a rebuttal on the Gauss/Maxwell question? You say I disagreed in the face of Richard stating that he lied? Sorry Art, you have me confused with someone else, because I know nothing about what you're talking about.

Walt, W2DU

Yet you joined in Walter in the party and the destruction of the
theme of what I was offering!
You are now saying you joined in without being aware of what was
happening? You knew then that Richard was a lier but it wasn't you
that was being harmed so it was o.k. Now it is you that is in the pot
and you are indignant because of his !supposed lies as well as being
surprised.
I don't accept your excuses of not being aware of what was going on
when you mimiced an englishmans banter when you rediculed what I was
offering regarding Gauss's law of statics choosing now to saying you
were unaware. Richard has ridiculed your position and your book now
but you are fortunate, he gave the reasons why and you have yet to

defend your positions with conviction even tho you are convinced he is lier. Now you realise how I felt where no reasoning was offerred for rebuttal only thrown missiles.You were aware of the lie and did nothing to correct it. I suggest you review all the postings that you made because they are still there.You can't run and you can';t hide as the truth is still there
prefering to jab at the heart. You know who you are and I know what you are

Cecil, W5DXP wrote:
"If we monitored only forward current or forward power at the antenna feedpoint, could we still adjust the tuner?"

Yes because a conjugate match delivers all available power (a maximum) and a conjugate match also exists at every pair of terminals between the transmitter and the antenna if the tuner and line are essentially lossless.

Best regards, Richard Harrison, KB5WZI

5608. feeding an 80 meter loop question

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-23 06:28:55 UTC
From: VK3XL <VK3XL.2a50e09@radiobanter.com>
Message-ID: <VK3XL.2a50e09@radiobanter.com>
Source record: 24730

Hello all, I am planning to erect an 80 meter full wave loop antenna in the back yard. The articals I have read so far all seem to feed the antenna at a corner with either 450 ohm open wire line or feed direct with 50 ohm coax. Due to the layout of my yard it would be preferable that I feed the antenna at the mid point of one side of the antenna with 450 ohm open wire line to a tuner (4:1 balun included in the line and coax to the tuner). Is there any disadvantage in feeding the loop mid way along one leg rather than at a corner?

any assistance greatly appreciated
Mike

Mike,
Is there a disadvantage? Not really, but maybe. Depending on the shape of the loop, it can/will change it's radiation pattern and polarization. That may not be of any importance at all, won't know till you try it.
- 'Doc

Hello Mike,

Nothing to worry about. Feeding at a corner or feeding in the middle
of the edge/leg has insignificant influence on radiation pattern (it
will be very good for NVIS operation).

The input impedance remains low (<<450 Ohm). Feeding with coax is
possible. Add a common mode choke to reduce influence of cable on
radiation pattern and local noise pick up. I assume that your loop is
almost square (so occupies large area).

Best regards,

Wim

Who cares.. You never gave any math to prove you are right.

>You never
> apologised either

Who cares... It's not his job to suck up to whiny little twits..

> on continuing what I am sure you knew was a lie because of your
> continual position
> of being superior in mathematics.

I take this as an admission that your math may even be worse
than mine is? :/

> The position you took makes you an
> accessory in the lie
> because you knew it was a lie.

But does he really care if it was or not?
I suspect he had better things to worry about.

>You and your book have been dissed even
> if you can prove that Richard lied again

This statement makes a lot of sense.. Almost
as much as a page full of your blabber about
equilibrium...

> but after the fact it is difficult to put things right. Instead of
> telling me to read your page why not read
> unwinantennas,com/ and the antenna group archives plus your own
> history on postings to refresh yourself on the "facts" that you wish
> for.

I suspect he has little time to waste on sub par physics, and
thus sub par antennas..

> If you wish to make a rebuttal on the Gauss/Maxwell question be my
> guest and point out why you disagreed even in the face of Richard
> stating that he lied or are you committed to deeply now to reverse
> course instead of revealing the truth because it may hurt?

Hey whiny one. I'm your huckleberry!!! I'm fairly bored at times.
I can keep you busy until next Christmas if you really feel the
need for discussion. I don't need any help from the others.
I'll brown your food just from shear logic, and I won't even need
no stinking math to do it.
IE: I'd still like to hear about how a "static" particle can move,
twist, and do the universal tango. And don't tell me that Gauss
or equilibrium had anything to do with it.
Doktor Davis.. Thats a laugh.. I remember everything about
that adventure, and Art, *you* are the liar about that case.
I've seen bumps on a persons ass that were more useful
than Doktor Davis was to your case.
Rather than answer a few pertinent questions posed to him,
he did the duck and run, and has never been heard from since.

Frankly, I kind of surprised at all the whining here.
I don't think Walters post, or articles, or even books are
out of the topic range of this group.
And neither do I consider Richard Clarks posts either.
For some reason they have a difference of opinion,
and I think they should work it out to hopefully come
to a conclusion.
They can do it in private, or right here. I could care less.
I haven't kept up with whatever led up to all this, so
I'm not taking sides at all. Both may have valid points.

Some of the comments seem a bit strong to me..
I find some of the comments to Walter as pretty tacky.
To me, the posts *are* on topic. A heck of a lot
closer than worries about the demise of Usenet,
perpetual motion theories, tennis shoes, touchtone
mikes, BIG BROTHER, etc, ad nausium..
Some of you all need to chill down and relax..
Go drink some vodka. That will help calm the nerves.
Works for me.. I like it with grapefruit juice...

But thats just my 29 cents worth.

How I got the extra 60 feet + up was to bring it back on itself towards the house in a shape of the letter V. The wire is very low to the floor and in every ones way. I have no idea how it radiates in this shape. It can only be like this as a temp solution.
I really need to understand why the End Fed wire is behaving the way it does. I think the Analyser is working OK or it wouldn't be able to tune a Centre Fed Dipole. I hope

When the earth rod was connected to the End Fed wire as a ground, there was a definite 2 S points up on received signal compared to it being disconnected. So it must be doing something.

I had a listen around 2 - 3.5 MHz for any strong signals and I can't find any that might cause me problems.

I would have expected the frequency to change when altering the length of the wire.

73 Andy.

Test Preparation Software

Pass your ham radio license test with ease. Our test preparation software serves as a training aid to help amateurs and prospective amateurs pass the VEC's administered test. When you can consistently pass the test given by our test preparation software, you will almost certainly pass an actual test.

Our ham radio license test preparation software uses the latest officially released VEC's approved question pools. The program breaks the test into different sub-element. Integrated into the software are illustrations and Part 97 rules pertaining to the current question. The program tracks the progress of the tests taken. Once you have mastered each sub-element you are ready for the official test.

Visit our web site at http://www.hamradiolicense.net for more information.

When used on higher bands the radiation pattern will vary depending on where
the loop is fed. There are too many variables to predict this without
computer modeling. You would be better off using 300 ohm line instead of
450. 300 ohm would more closely match the impedance of the loop on higher
bands and result in lower swr excursions but either type of feeder will work
great. The obvious advantage to corner feed is less sagging but your feeder
is lightweight.

> lossless.

I made an interesting assertion on a related thread over
on QRZ Q&A.

"A CONJUGATE MATCH TO A MISMATCHED LOAD GUARANTEES MAXIMUM
POWER REFLECTED FROM THE LOAD!"

The maximum available power is delivered to a mismatched load
when a conjugate match exists. It follows that is also the
point where the incident power is maximum and the mismatched
load will be reflecting the maximum amount of incident power.

Apparently, one could adjust an antenna tuner for a conjugate
match by monitoring the reflected power at the *output* of the
tuner and adjusting for a maximum. :-)

What you have done is essentially to add a counterpoise / radial which

is appx a quarterwave long. This is really the other half of the dipole. The higher it is up in the air, the more it will radiate. Note that, as it is at the top end of the 15 feet of 300 ohm feeder, the feeder will act like a transformer, and couple RF into 'counterpoise'. The 'counterpoise' will be more lively than if it were connected to the braid at the far end of the coax.

As the 'counterpoise' is coming back under the actual aerial wire (albeit at an angle) the radiation will tend to oppose that from the aerial. This will reduce the overall radiation, so the greater the separation, the better.

[Of course, if the counterpoise can be run in the opposite direction from the aerial wire, the radiation doesn't cancel, and you might as well erect the counterpoise as high as possible. What you will have, of course, is a 'normal' dipole.]

I still think all of this points to the fact that your earth rods are making very poor contact with the ground. If you have a fantastic earth connection, counterpoises and radials have little effect. With an absolutely lousy ground contact (and poor ground conductivity), they can make a great difference. With the single wire (and no counterpoise), the analyser will need a good earth connection. Without it, it's going to read rubbish, which may explain why a change of wire length makes no difference.

I think I would concentrate on improving the ground connection a bit more (more earth rods, or maybe some wires buried in the ground?). My inverted-L aerial feed is at the fence at the end of my back garden. The earthing system (at the fence) consists of three old bits of galvanized water pipe (about 6 foot long), and each about 6 feet apart. In addition to that, the wooden fence posts are mounted into 'Metposts'
http://www.metpost.co.uk/
each of which is about around 2.5 foot long, with only about 6 inches above the ground. The length of the fence is 70 feet, so there about Metposts. Most of these are also connected to my earthing system. I did once try adding a counterpoise for 80m, but it had no effect. [My soil, by the way, is mainly clay and flints. That which is not, is old bricks.]

When you've done as much as is reasonable with you earth system, all you can do is to add counterpoises etc.

If you really cannot get an efficient earth/counterpoise system, you will probably be better concentrating your efforts on dipoles (even if you have to use bent or compressed versions). At least you know where you are with a dipole.

For a loop, 20 m per side, 10 m above an average ground, the input
impedance is about 100 ohms (at 3.825 MHz). Feeding at the
corner, or the center, makes no difference to the input impedance.
The radiation pattern will rotate by 45 degrees. Very good high
angle radiation. At a 30 degree elevation angle the pattern is
like a dipole, with nulls about 4 dB deep, and max gain - 4 dbi.

73,

Frank

Your radiation pattern will probably change somewhat, perhaps to the better for what directions you desire. If you can model the antenna with software, this will give you somewhat of an indication.

Just for information, I have a horizontal 80m delta loop fed with 450 ohm ladder line which goes to a ferrite bead balun (W2DU style, built from a kit from Wireman) to go from balanced to unbalanced and a short (less than 6' coax) into the house to the tuner, an MFJ 941E. It tunes all bands 80m up through 10m very well and performs excellently. Not the greatest DX antenna, of course, but serves me well. Notice, this is a delta (three cornered) loop and not four sides, due to yard size and tree locations. I feed my loop about mid-side for convenience of feedline house entry.

I understand your frausteration with antenna discussions but it is
extremely hard to communicate the mathematical side of antennas for
anybody who did not reach the high school graduation point, especially
when you refuse to try to find out the meaning of equilibrium.
I just finished a explanation of my antenna work on Eham so you have a
chance to get up to speed on the subject rather than the spewing
remarks that reflect your fraustration especially when other more
experienced people are doing the same.

I used a three element 4-square 'loop' for years here. If your loop can or will be a vertical loop, even though the lower side of the square will be parallel to the earth and low to it, I can offer you suggestions.

Do *NOT attempt to feed it in horizontal polarization. You may go up midway on either side of the vertical wire elements. On one of them. all you have to do is attach the braid of the coax to the center point of the wire loop. Then, feed the loop with a gamma match segment made from, say six inch balanced line insulators which bind to the wire of the loop at the far end to the gamma line and through a variable capacitor to the center of the coax.

You tune the gamma match for proper SWR and so on and away you go with a really decent feed line operation to your rig. You can swing the coax to either the center support pole for it all, or move it perpendicular to the loop away from it in any direction off the the rig site. I believe you will be VERY pleased with the performance of the loop for DX purposes as the angle will favor vertical polarization, but you do not need ground support wires like in a vertical.

There are a number of references on how to more or less figure out the length of the gamma section.

Then, after you figure out the general value of the capacitor you need, you can pull off another stunt! You can use another chunk of your coax cable as a substitute for that capacitor! It has so much capacity for so many inches or feet. OK, you use the outer braid for one lead of you 'capacitor' and the inner wire for the other. You start with a little longer than needed or too much capacitance, then start snipping off the coax at the free end of this contraption to lower the capacitance until it is just right.

At the free end, be sure to leave an inch or so of complete coax insulation at the tip away out from the remaining braid. Then wrap it if you like with tape to keep out the water and so on. Zippee! Fixed very durable capacitor for this gamma feed device.

I've used this coax into capacitor technique for decades now on gamma matched verticals and so on. Never a problem ever with it.

The trick for getting low angle performance from large wire devices like loops on 40 and 80 is to get them to really be in vertical mode. And not dependent on the ground below for RF current return like in verticals that are ground plane devices.

But to do that you'll have to make the loop in a vertical mode, which, unless you choose to use loading coils to fudge the vertical height at the tips of the wire so you can keep the feed point balanced and a little lower, will require some kind of high support for the 66 foot or so vertical side of the loop at two ends of it.

I can assure you the fixed wire quads on 40 meters built this way have a VERY good signal and beam operation from personal experience. And their DX performance goes WAY up hotter if you feed them in vertical mode rather than in horizontal more the simple way down close to the ground.

Why would I need to know any math? You don't use or provide any
to inspect.
I know what equilibrium means to normal people. But you won't
provide any explanation for how you apply the term to antennas.

> I just finished a explanation of my antenna work on Eham so you have a
> chance to get up to speed on the subject rather than the spewing
> remarks that reflect your fraustration especially when other more
> experienced people are doing the same.

Yea, I checked it out.. What a hoot.. One ham invites you to provide
an on air test to check the performance of your antenna, but as
usual you ducked out with:
"I have no wish to get on the air to have a qso with you.
I have made antennas of all types using this aproach over the years
and presently have a 160 antenna made from multi interlaced wires to
make the antenna short physically."

You forgot to mention that you are either too lazy, or
basically too chicken @#$% to fire up the old rig and try it.
Pathetic...

Another requested plans so he could make one for himself.
You replied with:
"I will be happy to do so. But first the background.Antennas are
based
on Maxwells laws and the equations use the term root L.C."
But then had no further mention of providing any plans.

I also saw one thread where you were corrupting the mind of
some newby ham with your irrational drivel..
Shame on the mess...

Show me one place where you use math to explain your design.
You can't because you don't use any.
So explain to me how this would fraustrate me, whatever that
means. If anyone around here is fraustrated, it would be you.

I dislike the way you slandered John E Davis ! He has only made a few
posts on this newsgroup which are readily obtainable.
He posted on this newsgroup purely to provide the equality of
mathematics of Maxwell and Gauss for which he is qaulified with a
doctrate from MIT working on astral matters for NASA. He made several
attempts to explain the math even in the face of caustic comments from
this group. After he had supplied the mathematics he then left the
newsgroup. He did not cut and run. He did what he set out to do and he
did it extremely well.
Since that time, months,Richard admitted that what Davis said was
true. No. He said of course it was true. Others that followed Richard
in that lie have never recanted preffering to continually to pljunge
the knife. I suggest you recover John's posts on the mathematics and
apologize

I don't care if he's Navin R. Johnson, he was still useless to
your cause.

>He made several
> attempts to explain the math even in the face of caustic comments from

I don't recall him giving out any math at all.

>He did not cut and run. He did what he set out to do and he

You are not in a position to suggest anything. You can't even get
off your rear to fire up a rig and test an antenna when requested
to do so. If this were not the case, you would know your antenna is a
pseudo dummy load from prior experience, and we wouldn't be having

this usenet QSO.

Maxwells law states for efficiency the antenna sysystem must be in
equilibrium.
Equilibrium means that the antenna or antenna system must be a
parallel system because it represents
a full wave length.The transmitter adds a parallel circuit to the
system but it does put stress on the output if the antenna is not in
equilibrium.
It is thus better to keep the stresses away from the transmitter and
contain them in a separate tuner where excess power can slosh
backwards and forwards in the tank circuit, this helps to prevent
expence damage to the finals If you want the antenna system to finish
at the antenna feed point area then you place the tuner at that point,
where it is still part of a antenna system because it allows the
antenna only the power it needs for saturation and where the excess is
circulated in the tuner. If you want the antenna to operate without
the tuner then the antenna will resort to a system where with the

inclusion of a ground system and feed system will act as a heat sink in the absence of equilibrium at the antenna. When you want the antenna to radiate the energy it is supplied then it must be in equilibrium where the distributed loads provide a tank circuit for efficient radiation without saturation overkill. Remember that what radiats is a full wave length of wire wether it is all on the antenna or the antenna spreads the excess to the tuner and the feed system. You cant stop the radiation you just try to ensure the excess doesn't create damage when it turns into heat

Not that this is particularly relevant, but while training to be a Marine Radio Officer many years ago in central London, a message was received from the coast station at Dover requesting that we cease test transmissions on 480 kHz as we were causing interference to maritime coast station operations. The transmitter was running less than 80 watts CW into a fully screened dummy load at the time! This is a distance of around 70 miles as the crow flies.

Art's antenna apparently contains what would be several wavelengths of helically wound conductor at any HF amateur frequency (I recall seeing a figure of 2000 feet mentioned). I see no reason why it wouldn't radiate considerably better than a dummy load in an earthed screened box. If lack of real estate means you have to use miniature antennas, it doesn't matter what you use if it gets a signal out.

As I see it, Art is claiming that his antenna is a no tune, all band antenna which is very compact and efficient for it's size. Experience suggests to m that the radiation efficiency is nowhere near as good as a full sized resonant or beam antenna and I doubt that new physical principles are involved. Experience also suggests that the sheer amount of wire in the antenna will present an acceptable match to most transmitters at HF frequencies and above. Dummy load or not, if it is radiating even a quite modest signal at low horizontal angles, it will suit many urban dwellers and give relatively good DX performance for its size.

It really doesn't matter what the maths are or whether exotic new physics is involved. If you stick a couple of thousand feet of wire up in the air (even wound in a coil) the system is going to put out a signal.

This forum often degenerates into meaningless discussions as to the exact meaning of a word, phrase, or measurement and specifications used. While this might be necessary for a rigorous scientific analysis, the clue is in the name rec.radio.amateur.antenna.

Don't get bogged down in meaningless minor theoretical details. Does it do what is claimed? Yes or no. Job done.

Regards

Mike G0ULI

I am in full agreement except it needs clarification regards the tuning portion. Yes it has a reasonable impedance at scource for all frequencies and thus will radiate on all frequencies. For amateur use they would want to choose a wavelength as the basis for equilibrium because of gain and bandwidth effects. So for a spot frequency it is better to jumper to the wavelength of the frequency of choice. I by choice have several jumpers while at the same time using a variometer to accommodate frequencies that do not exactly match the jumper positions.Computer programs show that you can obtain gains with multiples of wave length similar to a helix where the windings must continue back to the feed point so that external lumped loads are cancelled to bring the array into equilibrium, which means that multiple wavelength unit can be used to advantage., I still haven't found out why Maxwell did not emphasize the equilibrium status when all that provided formulas for his work all emphasised Newtons laws. I do know that he wrote a paper on equilibrium in his later years but I have found no evidence he went back to add it to his prior law(possibly he wanted to place his own mark on the formulae that he garnished from others) One last thing I want to emphasise.
For TOTAL gain it matters little if you use a yagi or a non planar arrangement the difference comes into play where the need is for a maximum gain of a particular polarity where equilibrium comes to the fore.

Exactly.
But he garnished laws for his use that were all based on equilibrium
as stated by
other masters as the basis of their findings.
I gave one sample of this by mathematics and the use of Gauss's
theorem to show that Maxwell encompassed the effects of equilibrium
without the verbalisation. Another point I would make about
equilibrium that its very existance defines the lack of moving charge
on the innards of a conductor to achieve Newtons law of action and
reaction where skin depth comes into being as part and parcel of that
concept.. Another point where proof comes into place is that the
computer programs show that for maximum polarisation of any kind and
antenne is not verticle or at right angles to the earth because of
vector values that are encompased by equilibrium. So yes, the premise
of equilibrium is firmly planted in Maxwells laws because of its
content in other laws that he mathematically, which was his interest,
manipulated regardess of their origins.
If one used the Gaussian extension that I used in place of Maxwells
laws it can be readily seen that radiation is created by the movement
of particles, evidence that Maxwell could not and did not supply thus
leaving a void for Einstein that forced him away from classical
physics.
So yes, Maxwell made a huge error by not mentioning the requirement of
equilibrium per Newtons laws.

5632. interesting format for a new antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-24 01:52:19 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <d37f49fd-c56e-44e8-bba3-2e26dd914a14@f36g2000hsa.googlegroups.com>
Source record: 24654

When reviewing the shield of coax I see that the circulating strands
follow the same principle
that I advocate for small full wave antennas. Each turn on the
shielding has a compensating return
turn which cancels the added inductance while the wire crosses over
each other to cancel the added capacitances.
If one got a short length of say 2 inch diameter sheathing they could
attach the wires into one complete circuit
for an antenna. One could dip the sheathing into some sort of
insulation if they so which but actually the wires each act as
insulated wire (electricity preferrs not to turn at right angles if it
can go straight) so that is really not necessary . If you feel the
need to experiment on a mobile whip that does not require a ground
plane then here is one that is full wavelength and really small
compared to a Bug catcher ! Give it a try and take it to the next club
meeting.

5633. Does a HF vertical antenna need a balun?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-24 02:18:18 UTC
From: Nick <nick.adams95@yahoo.com>
Message-ID: <c8cc7c9f-cbe5-4d74-a2a2-96a5b7efadc0@w1g2000prd.googlegroups.com>
Source record: 24655
Cross-posted to: rec.radio.amateur.antenna,sci.electronics.design

Hi All,

I keep reading on various websites and in various documents that HF verticals should have a "line isolator" (a choke/current balun) located near the antenna's feedpoint to prevent coax feedline re-radiation, disruption of the antenna's radiation pattern, sub-optimal vertical performance, and RFI in the shack. My question is this: just how important is a choke balun when using a ground-mounted HF (for 40M) quarter-wave vertical antenna with 32 quarter-wave buried radials? And if it is important, why wouldn't the choke be placed at the shack's input, so that the coax's outer shield could act as another radial? (I had always assumed that a vertical didn't need a balun at all, and that only dipoles used them. Am I wrong about this?).

Thanks!

Nick

Hi Lumpy you are a blast of fresh air!
On this group a common remark is
"I wish you would check out the facts first"
This is in other words is the expert telling you that you must agree
with him.
This is really the basis of this actual thread where a book writer is
angry
because people publicly disagree with him and his writings. Read my
book it is authoritative,
no I don't need to read other peoples pages or work! or "I don't
recall that"
which parallels cover for lies in Congress and in talk groups.
I have been a big gun with a 80 foot long multi element yagi but now
the talking side lags
behind the design of small antennas so all can enjoy"I was always told
that you must supply the math first
before you make a claim. Now I find that when the math is supplied
they state they don';t understand

or are convinced that one plus one is three! There is no way a ham
(self perceived expert) on this group
will accept that all is not known and I am the one who knows it all.
Which is why they dissed that Doctor from MIT and NASA
who provided some mathematical data that they disagreed with. Ofcourse
one and one equals three, the majority on this newsgroup agrees on
that so you MUST be wrong. On top of that we are the experts no less!

Thanks all who have replied to my question. I am glad to hear that there are no serious detrimental effects of feeding the antenna mid way along one side rather than at a corner. I should have mentioned that I am intending to make a horizontal loop antenna rather than a vertical. Another interesting point came out of this, a delta loop may provide a better fit in the space available when the tree locations are taken into account. Again thanks for the info

I think line isolator is slightly different from balun. Here line
isolator would be necessary for lightening protection etc and hence
better kept at antenna base. Balun is for converting a balanced
structure like dipole antenna to unbalanced structure like coax. Since
monopole antenna is unbalanced structure it does not need balun at its
input.

Thats the whole problem. If he just offered the design as what it is,
instead of what he fantasies it to be, I would have no problem.
It's no secret that almost anything will radiate to some degree.
Many people have made QSO's using nothing but dummy loads.
I have no problem with this.
Why? Because they didn't build a dummy load, and then proclaim
it as some new breakthrough in science.
It Art designed and built this antenna, and offered it to the public
as is, without all the pseudo science bafflegab, he would never
hear from me.
I wouldn't even care that he never actually tests the antenna.
But nope.. Art doesn't play the game that way.
He uses a modeling program to conjer up all kinds of weird
designs, and then uses the optimizer programs to try to get
maximum gain, or whatever he is trying to find.
He cooks up a particular design, decides he likes it, and
then reveals it to the world as some exotic new design,
which uses exotic theory, which only Art and some obscure
doktor from MIT can understand.
He can not explain these designs using known theory, so
he cooks up page after page after page of nothing but
pure unadulterated bafflegab to try to explain how they
might work.
This is the problem as I see it.
Heck, I might not even have a problem with that alone, he
wasn't so insistent that his "theory" is indeed fact.
I check all his pages and he provides NO math at all.
But he continues to whine about math.
I have read the Doktor Davis thread several times since
it was posted, and he provides NO math to explain Arts
design. And he did duck and run when it was suggested
that he was misreading the data. Instead of giving an answer
one way or the other, he vanished, never to be heard from
again.
Art refuses to do real world tests. He refuses to actually

try the antenna on the air to do comparisons with a
known antenna such as a dipole even when invited to
do so by other hams.
He'll always offer some lame excuse as to why he refuses
to do so. Either that, or he reverses the invitation to make
it appear as an attack on poor old Art, the man who
the phrase "woe is me" was apparently written for.
.
I've told him several times to just build the thing and let
the chips fall where they may.
He seems to build a few, but he never gets to testing
how the chips may fall.
He sent one to a ham on this group, and we never heard
a peep since. If it was the "miracle whip" it was made out
to be, seems to me the word would be out by now.

Well, excuse the @#$% out of me if I don't fall in line
and do the goose step along side of him in an orderly
military manner. :/

A "line isolator" (a choke/current balun) will provide no lightening
protection.

What is being talked about is a choke to prevent currents from flowing on
the outer of the coax.
It is not a balun in the purest sense, but it does stop unbalanced currents
from flowing on the coax.

The problem with an HF vertical is that the ground plane will never be
anywhere near prefect, so it will
not be possible to feed with coax without some current flowing on the outer.

I guess the only problem with putting the choke at the antenna base will be
pickup onto the outer as is
crosses the groundpalne. so I can see the idea of putting the choke at the
edge of the GP might be better.

I guess it either suck it and see, or try to simulate it with NEC.

Does this mean that if one places his finger on a live wire while making
sure to keep said finger at right angles to the wire that no shock will
be delivered? Do ordinary electricians know about this protective strategy?

It's not a balun in ANY sense of the word. Some of the manufacturers of
the 9:1 isolation/semi-matching transformers (essentially for listening
only) persist in calling these 'baluns'. But baluns they ain't.

Unfortunately, 'balun' has become a generic word for many types of RF
transformer (especially those wound on ferrite). It's a bit like calling
all vacuum cleaners 'Hoovers' - which is what we do, at least in the UK.

With this type of antenna, it certainly is not common practice to
choke/isolate the coax, especially the coax braid can be grounded at the
antenna feedpoint and in the shack, and possibly at some intermediate
points along its length. It wouldn't do any harm to use one, but it
probably wouldn't do very much.

Thanks for all the great responses guys! That is exactly what I had thought, that since the outer coax braid is grounded at the antenna, and at the shack, and (in my case) at the center with a lightening protector, then I just couldn't figure out why some antenna companies, such as reliable DX engineering with their DXE-VFCC H05-A Vertical Feedline Current Choke, strongly recommend such a line isolator for verticals. A direct quote from DX Engineering's Website:

"2/5 kW Vertical Feedline Current Choke
If your antenna SWR is already low and you wish to reduce feedline radiation and improve reception, a Feedline Current Choke is recommended. Adding a DX Engineering Feedline Current Choke at the base of a vertical antenna will substantially reduce unwanted feedline radiation (RFI), reducing the need for improved station grounding.

When quarter-wave antennas are constructed over a good radial system, they have a feedpoint impedance of about 36 ohms. When they are constructed over less than a good radial-system there is a loss introduced into the feed system that adds to the 36-ohm figure. This improves the SWR but there is a loss in the efficiency of the antenna, signals transmitted and received have a higher take-off angle and often there is current introduced on to the feedline.

With a ground-mounted quarter-wave vertical, regardless of the radial situation, but especially with poor radial systems, the feedline can become part of the radial system, causing RFI and poor antenna performance. By using a VFCC at the feedpoint, the feedline is effectively de-coupled from the antenna system, preventing interaction with the radial system, improving antenna efficiency. You may notice improved bandwidth as well.

The Advantages of Using a VFCC:
Prevents unwanted RFI by eliminating feedline current and radiation
All power goes to the antenna, improving efficiency
Reduces noise or unwanted signals picked-up by the feedline
Overcome a less than optimal ground system
Bracket isolates the VFCC case from ground for best de-coupling"

This is good, as far as it gets to this point, but...

>signals transmitted and received have a higher take-off angle and
>often there is current introduced on to the feedline.

Take-off angle is dictated to the quality of ground 5 to 10
wavelengths AWAY (and further) from the antenna.

You could, if you so choose, build 120 radials out 20 wavelengths to
achieve their implied claim of radials contributing to lower take-off
angles.

>With a ground-mounted quarter-wave vertical, regardless of the radial
>situation, but especially with poor radial systems, the feedline can
>become part of the radial system, causing RFI and poor antenna

For a transmitter, it is unlikely that the listener could tell the
difference between operating into that "poor radial system" and adding
the a vfcc.

>By using a VFCC at the feedpoint, the feedline is
>effectively de-coupled from the antenna system, preventing interaction
>with the radial system, improving antenna efficiency. You may notice
>improved bandwidth as well.

This contains a contradiction when it gets to the "improved
bandwidth." Presuming that means wider, it then means more loss. More
loss would come from NOT using the vfcc (or why buy one?).

>The Advantages of Using a VFCC:
>Prevents unwanted RFI by eliminating feedline current and radiation
>All power goes to the antenna, improving efficiency

Uh-huh. Again, will the listener be able to tell? A radiating feedline might boost their gain - who knows?

>Reduces noise or unwanted signals picked-up by the feedline
>Overcome a less than optimal ground system
>Bracket isolates the VFCC case from ground for best de-coupling"

The noise pickup is the more likely benefit (along with the remote ground - tied into the service ground as required by code). House noise can travel down the outer portion of the shield to then develop across the load of the antenna, and then wrap around to travel back inside the coax to the receiver. A choke will snub this path and the remote ground will lower the resistance. The divider action suppresses local noise.

The same benefit can be obtained from a $25 purchase of bulk ferrite beads (about 50 of them) which are fitted over a one foot length of RG-58 (or the distal end of your feedline).

Get the best of both worlds. Put one choke at the antenna
base and one more 1/4WL down the feedline which will be
close to your "edge of the GP".

Nick, think about it. If you ground the feedline at exactly a
common-mode standing wave voltage node, the ground accomplishes
absolutely nothing. You certainly don't want to use "plumber's
delight" techniques in your ground system.

Any specific citations? I've got some papers on Litz wire, but haven't found any on braided wire where the component wires are uninsulated.

There's a paper in 1916 Proceedings of IRE by Kennelly, et al., "Skin-Effect Measurements of Conductors, at Radio Frequencies up to 100,000 Cycles per Second" But that's litz wire, not bare strands

W.A. Johnson, et al., published "Static modeling of periodic structures with application to braided shields" in the APS Symposium 2004, but they assume perfect conductors.

H. Haase and J. Nitsch published "High frequency model for the transfer impedance based on a generalized transmission-line theory" in IEEE Intl symposium on EMC in 2001. They model the braiding, but make the thin wire approximation for the wires, and take limited account of the proximity effect (like skin effect, except effect of a wire on an

adjacent conductor)

There's a host of papers in IEEE Trans on EMC, but none of them seem to make the assumption that the wires are insulated.

in fact, a paper such as the 2003 one by Tiedemann in IEEE Trans EMC, v45, #3, "Current Flow in Coaxial Braided Cable Shields" makes the comment in it's conclusion: "The interactions between the single braid wires are very complicated"

However, Tiedemann DOES say that the shield is better modeled by insulated wires than as a uniform tube, at least as far as shielding effectiveness... (he looked at 3 kinds of RG-58 from DC to 500 MHz)

FWIW, Tiedemann is probably hot stuff on this topic.. His PhD dissertation was "Schirmwirkung Koaxialer Geflectsstrukturen", TU Dresden, 2001

Jim, I put into google "insulated wire coax IEEE" as near as I can
remember
The abstract stated that the wire acted like they were insulated!
Came across another one that gave the same comment.
I would point out that I am referring to an abstract only as I am not
privy to the whole report
Would appreciate any clarification
Regards
Art

Thanks Richard and Cecil.
Cecil, I understand what you are saying, but still why not use the
outer shield of the coax as one of the radials, and simply choke off
the coax just before it enters the shack? I also don't want to add
what may be a useless choke at the antenna's feedpoint, since that
would decrease the antenna system's efficiency due to the choke's
resistive losses...

Thanks!

-Nick

Hi Nick,

A choke at the feedpoint does NOT add loss.

The Choke (which may be resistive insofar as the bulk material's property) is in the Common Mode circuit. The load is in the Differential Mode circuit. You want a very, very high Z (or R, it makes no difference) in the Common Mode circuit. The choke is entirely transparent to the Differential Mode circuit.

If you don't understand the difference between the two modes (and it is not a common topic outside of electronics design) then, no doubt, others will fill in (or simply go to wikipedia).

Thanks for the further info Richard! I guess I don't really fully
understand why the pure resistive losses in the coax choke wouldn't
affect the efficiency of the monopole. If I understand you correctly
(and I may not!), then even if we increase the impedance of the coax
choke to insane levels, such as by making it 1000 feet long and
winding it on a six inch diameter PVC form, then the huge losses
normally inherent in such a long run of coax would not be seen at all
by the vertical because it is wound on the PVC form? (I'm not arguing
with you at all, I just really want to know).

73,

-Nick

Hi Nick,

Well, no argument perceived. 1000 feet would come with its own loss. This is published in dB attenuation/100 feet for almost any type and grade of coax in the market (and those that are no longer made). This is truly Differential Mode loss.

Winding too much into a coil would not necessarily achieve the results expected due to self-resonance (it could act like a shorted choke, and not very useful). You can achieve astonishingly high Zs with a coiled transmission line with very little effort (roughly 8-12 turns on a liter pop bottle - empty of course - for HF). It will peak at some frequency and provide adequate isolation in nearby bands; however, the ferrite chokes can be made to cover a decade of frequency - or much more (3-30 MHz), if you care to really go whole hog (3MHz-3GHz) with 1000 Ohms of Z (principally R) without too much effort either (more cost than effort I should add).

One proviso should be observed: Whatever problems find their way onto the shield of the coax (Common Mode circuit) can arrive over the air. If they do, they can induce themselves into the below the choke point as easily as at the antenna. The solution here is to repeat the choke construction 1/4 wavelength from the feedpoint (a second choke, that is). If you are choking a wide band, you might try distributing the ferrite beads over a greater length of coax than the 1 foot it would normally inhabit. I have a 20 foot ferrite choking section that I can insert, inline, into my feeds. It has one bead every 3 or 4 inches. I wouldn't advise this as replacing the feedpoint choke, but rather the

second choke some short distance away.

Note that I made a distinction about interference coming in "over the air." This is not the only way as most home based interference comes into the receiver by conduction - sharing a poor ground. Most folks who swear that chokes don't work (or at least theirs don't so none do), are suffering from ground loops. A choke can help, but not nearly as well as combining it with conventional grounding solutions. Poor advice abounds in this topic too.

A simple way to think of it is: Ferrite beads over the outer of a coax has
no effect on the signals flowing 'normally'
up and down 'inside' it. The beads only effect signals that are flowing on
the outer (treating it like a piece of wire rather
than a coax transmission line). I know that this is not quite the full story
but it is a simple explanation of the situation
under discussion.

It may once have been an established convention to bottom post - these days many people don't bother unless there is a specific need to reference particular comments in multiple parts of a posting. May be irritating for some, but build a bridge and get over it.
A more serious PITA is people not trimming the unnecessary parts from their responses when there is no requirement to include it. If people really want to have a look at how the discussion plays out, then they can go back and look through it, post by post. Much more of a PITA to have people include a couple of hundred lines of text - or more - and then reply with a couple of words......
As to the actual topic of the post, yes, the analyser might be picking up a strong local transmission that is confusing it - having said that, at my current QTH, I am pretty close to a number of MW broadcast sites with high TX levels and I have not experienced any of the problems or issues as outlined by Andy.

Unless the coax is up and in the clear, common-mode power is
probably wasted whether you choke or not.

If your choke at the shack happens to be placed at a common-
mode voltage-maximum/current-minimum, it will be ineffective.
One reason for placing a choke at the antenna feedpoint is
that is probably the maximum current point where the choke
has a good chance of being most effective.

Am I a hopeless noob, or are there a lot of things wrong here?
Feedline radiation = RFI. and almost a lure toward poor station grounding?

> When quarter-wave antennas are constructed over a good radial system,
> they have a feedpoint impedance of about 36 ohms. When they are

Are there tests showing this somewhere?

Anyway, you are probably best served by placing as many radials as you
can handle - but more than 4. I just went till my knees and back said
"no more", then came back the next day and laid more. Have as good a

grounding system as you can get, and good lightning protection. IMO, if that isolator is helping any, it is just trying to mitigate a problem that should be taken care of elsewhere.

Thanks again guys. I'll have to study common versus diff mode
currents on coax cable again to gain a better understanding of the
situation! And as was stated by many, a good radial field should
mitigate the situation anyway.

5671. Transmission line choke - re:Richard Clark

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-25 16:17:18 UTC
From: John KD5YI <groups2_dot_jocjo@xoxy.net>
Message-ID: <icu8k.2$BR.0@trnddc06>
Source record: 24693

In another thread, Richard said:

"You can achieve astonishingly high Zs with a coiled
transmission line with very little effort (roughly 8-12 turns on a
liter pop bottle - empty of course - for HF)."

The key is "...empty of course...". What if one were to fill the bottle with relatively pure water to keep dissipation factor low? Water's dielectric constant is about 80. This would increase the stray capacitance, thus reducing the required turns to achieve resonance. Would this increase the Q due to lower loss in the inductance?

Just curious.

John

Very unlikely. It won't increase the effective shunt capacitance all
that much since it's not between the turns, and it's not likely you'll
have pure enough water to have low loss in the water.

You can wind a coil that's self-resonant and achieve a high impedance
over a fairly broad range of frequencies (that is, across all of an HF
band), or you can use just a few turns (that is, a coil whose self
resonance is considerably higher than the operating frequency) and put
a tuning capacitor across the coil and tune it to a specific
frequency. That can be nice at lower frequencies where it takes a
long piece of line to make a self-resonant coil. In that case, the
impedance at resonance will be high, but the bandwidth will be
relatively small; it can use a lot less coax though. There are
programs and web sites that predict the self-resonant frequency of
solenoid coils, though with the coax jacket, expect the actual self-
resonance to be slightly lower than the same coil without the jacket.

Cheers,
Tom

Hi Tom

What do you suppose would happen if the bottle had some steel wool in it
and (maybe) have a few less turns?

Jerry KD6JDJ

art gets his info from reading abstracts... that figures. by the way, that
abstract doesn't say:

> >> the wires in
> >> braiding act like insulated wires.

as art states, what it says is "the standard braid of the shield used had
the same properties as a braid made with insulated wires." these are not
equivalent statements. indeed a simple resistance test would instantly tell
the difference. without knowing the range of frequencies and 'properties'
that were measured in the braid you can't just make a blanket statement that
"the wires in the braiding act like insulated wires". try reading some full
journal articles and whole books art, not just the dust jackets.

Well, shoot, if you put enough (common-mode) current in the coil, you might be able to get the steel wool to catch on fire...

Honestly, I've had good enough experiences just using "air core" coils of line as chokes, and in rare cases where I had a lot of RF to get rid of putting a resonating capacitor across the coil, that I haven't ever found it worth worrying about putting things into the coil as a 'core'. At this point I should perhaps ask, is the choke intended to be dissipative, or reflective? Should it be just a high impedance so very little current is allowed at that point, or should it look like a resistive load? My ideal is high impedances at enough points along conductors that aren't supposed to be radiating that the currents on those conductors remain low.

Cheers,
Tom

I have a Directv dish 35 inches wide x 20 inches tall 4inches deep.
I calculated the focus as F=D*2 / 16d where D =diameter and d=depth
F=18 inches Ok so far.
How do you find beamwidth? I think the 35" dimensiom would have a tighter
pattern than the 20 ", but how do you calculate,

Second, The feed antenna, There can be different feeds.
A simple monopole, dipole, biquad, patch, yagi, helix.
How does the feed antenna affect the gain of the dish, if at all?
Yea, it my be difficult to light the yagi or helix, so if you like throw
those out.
Thank You,
Mike

You have a neat gadget here!
If you place a lamp (flashlight?) at the focus you can measure the
beam on a wall wth a tape measure.

Put a microphone at the focus and you can hear things you would not
believe...

Old ARRL antenna books, and authors like John Krause will be needed
to answer all of your questions.

I found 6 feet of RG58 and an empty plastic water bottle of about 2.7 inches
diameter. I got 8 close-wound turns of the coax on the bottle. I used my
Boonton Megacycle Meter to measure the self-resonant frequency of 43.8 MHz

with the bottle void of water. I then filled the bottle with distilled water. The new frequency was 24.1 MHz. Wow! This is an increase of about 3.3 times in the stray capacitance. Even with the dielectric constant in the center increasing 80 times, I didn't expect such a dramatic change.

The real question of Q remains unanswered. This was a quick test to see if there may be enough change to warrant further study. But, it occurs to me that the weight of the water would be entirely prohibitive if one wanted to hang the water coil from an antenna.

Is there any place this might be used where the weight would not be a problem? Does this warrant a closer look to measure Q?

John

It grey, won't reflect light very well. Basically I wanted to know how the
beamwidth changed with the larger width dimension vs the smaller height
dimension

> Put a microphone at the focus and you can hear things you would not
> believe...

I already experienced the reflection. I had a radio playing on my right
side, I was moving the dish and got an increase in volume in my left ear. I
moved the dish back
to play around with the effect. Neat!

The DirecTV dishes are not prime focus, bu rather offset. If it came with
the original horn mount, use it.
You can use:
http://www.w1ghz.cx/software/hdl_3b4.zip
to find the focal length,. Your formula assumes prime focus.

The gain of the dish is not a function of the feed, but the system gain is
because one must take into account surface illumination, feed efficiency
etc.

The subject of feeds for dishes is complex if you really want to optimize
G/T etc. Paul W1GHZ has a teriffic on-line text about parabolic surfaces and
feeds:
http://www.w1ghz.org/antbook/preface.htm

Hi, Mike.
I have been using a 160 meter, horizontal, almost square loop since January. It is suspended from four 36 foot push-up masts at about 33 feet. It is fed at a corner with 125 ft. of home made 600 ohm feed line. Works on all bands with an antenna tuner. Even made a couple of local 6 meter contacts.

The challenge is to get each of the 4 wire legs under the same tension. The connection of the antenna wire to the corner insulators must be able to move so you can get it all evened up. Once up, the back stay at the top of each mast, along with the 90 degree antenna wire make for a very stable installation. The fierce winds we sometimes have in Central Oregon hardly move the antenna wire.

I made the corner connectors out of a circular piece of brass by milling a circular slot about 1 inch away from the center of the circle. Then cut the circle into 4 sectors. I machined 4 brass covers to fit over the slot after the antenna wire is placed in the slot. The covers are held by 4 small socket head cap screws. Anti-seize compound protects the threads from rust. A hole is drilled in the back of each brass corner piece to connect to the ceramic insulator. I cut lengths of heavy copper wire and after putting it through the insulator and brass corner piece, pounded the ends flat. The heavy wire was formed into a loop with overlapping ends. The heavy wire ends were then drilled to accept a small machine screw and nut to hold the ends of the copper wire loop.

The top of each push up mast has a pulley and 1/4 inch rope to pull up the antenna corner. Several trial runs were made get it all up in the air and get the tension pretty much equal.

I think you will like your antenna a lot. Good luck with it.

Hello Mike,

In case of uniform illumination, gain is maximum, side lobes are
maximum also and beam width is about 60*lambda/diameter (degrees).

You will certainly not reach this, for several reasons. The beam width
will be more, it can be twice as high (depending on the illuminator).

The maximum gain that you can obtain with a certain aperture antenna
is about 4*pi*A/lambda^2. In reality it will be less:

When you want uniform illumination, you will have "spill over" (part
of the radiated power will not reach the dish). To get most power onto
the dish, you must accept that the edges of the dish do receive less
power flux density.

In addition, the phase center of your illuminator will change versus
off-main beam direction. This causes phase differences so a non-planar
field. Also polarization may change for off-beam directions.

Other things are deviation from optimal parabolic shape, non correctly
positioned illuminator, etc. This will all reduce maximum gain.

Hope this helps a bit.

Best regards,

Wim

Yes, it is an offset feed and it did come with the mount and feed (LNA?)
Actually it came with two LNAs, but they didn't match each other. I don't
remember what junk pile this came from and don't have any info about it's
working condition.
I did measure the distance from the front of feed to the dish center and
it is 18" as calculated, however as I said I don't know if this worked as I
got it.

I'll look at the w1ghz link.
I was suprised this dish is made of plastic. Does the EM wave reflect off
of the plastic or does the plastic have a coating?
Thanks, Mike

Hey I just found the dish I have it's at
http://www.solidsignal.com/satellite/directv_dish_antenna_types.asp
Last dish on the right side of the page, it's called the International
Satellite Dish.
International 36". I note from the picture the feeds don't match, when I got
the dish
the position of the two feeds were reversed.
What can you glean fron this?
Thanks, Mike

It is possibly an aluminium foil reflector sandwiched between 2 layers
of plastic.
I have a 1 metre dia sat dish with the aluminium foil sandwiched between
2 layers of fibre glass/epoxy.

My dish is 35" wide x 20"tall
So if Lambda=4.89" Then 60 x 4.89 / 35 = 8.38*
and 60 x 4.89 / 20 = 14.67*
Then my beamwidth will be taller than it is wide.

> You will certainly not reach this, for several reasons. The beam width

Yes. it's always something.

Some guys at the local club were trying to use a TV dish like yours.
They eventually decided it was easier to build a dish from scratch.
The old TVRO dishes can be useful and there are plenty of them around
that can be had just for the asking.

5698. Need help with first HF antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-27 19:20:20 UTC
From: Keith <none@yahoo.com>
Message-ID: <g43eheuhf1@aioe.org>
Source record: 24619

Finally upgraded to General this winter, and found a Ten-Tec Triton IV (my first HF rig) and I need some antenna help.

I need something simple that will give decent performance, and keep XYL happy.

Some ideas I've come across:

1. A random loop strung in a few trees, fed with ladder line to ground level, with a balun and lightning arrestor, into buried coax 50' or so to the house and into the shack. This setup is the most aesthetically pleasing, and coax will be easy to run in the house. How much will the transition to coax hurt me here? Would I need a 1:1 or 4:1 balun? Some other ratio?

2. Same random loop, fed with ladder line all the way into the shack. Would probably give better performance, but running the ladder line in the house will be more difficult, and the XYL is less likely to approve of a wire in the air vs buried.

3. A dipole in one of the above configurations.

4. A random long wire strung around the yard, end-fed with coax and a balun.

I will be using an antenna tuner in the shack with any of these configurations, and will be running a max of 100W for the foreseeable future. How much do I have to worry about the wire touching the trees at these power levels?

Thanks for any help you can give - I know these questions have probably been asked a million times before :)

Gee, getting relevant information from you is a chore, and you seem to delight in supplying a partial picture.

Now, what frequency WiFi?

If you are thinking of 2.4GHz, you must already have worked out a feed solution that efficiently illuminates the small dish, a considerable challenge.

While you are obsessing about calculating the area of an elipse, you haven't had a look at the disk from the distant end, have you? It is probably very close to circular in cross section when viewed from afar in the direction of the beam.

When you have worked through some of this, you might see why offset feed dishes made for Ku band aren't widely used by informed people at 2.4GHz. Of course, there will always be the 'innovaters' with a USB wireless stick pointing at a garbage tin lid or wok... but that says it all, doesn't it!

Keith,
Nothing wrong with any of your suggestions, but why not start out very simple, as in a dipole. It will at the very least give you something to make comparisons against. When your better half sort of gets used to the idea of wire hanging in the air, then you can make changes. You might even ask her what color of wire she thinks would be 'best'. No, it won't make any difference except that it shows that you respect her opinion... sort of. (If she reads that last part, you are up that proverbial creek!)

You will probably find a lot of help if you "nose" around your local college (computer/physics/engineering instructors can point you to the best minds.) The youngsters are all into stretching wifi distances to the max.

Here is a page to get you started:

http://www.engadget.com/2005/11/15/how-to-build-a-wifi-biquad-dish-antenna/

After experimenting with many different antennas at the feed point, I kept the biquad in the original plans. Your dish is larger than the one I use (mine is identical to the one on the page--my feed is slightly modified ...)

I just put up a 66' center fed zep, fed with 450 ohm ribbon line.
This line goes to just outside my radio room where it terminates into
a 4:1 Home-made (off the www) balun, coax feeds into the house to a
Nye tuner. Easily tunes 80 to 10 mtrs & works good.
Many good ways, this is just one!

The fact that its constuction secrets are not all over the internet speaks volumes. If this were truly a decent antenna there is no way the genie could be kept in the bottle.

I would have to go with you on this one.

If this design/performance was good many large companies and commercial interests would have already picked up on it. Indeed, if this were half of what it claimed, there would be no need to market it to individual amateurs or use marketing tactics which smack of such secrecy, mystery and magic--the money from larger users would just make these ideas laughable.

It seems obvious, if it is marketed like snake-oil, if it comes in a snake-oil-bottle, if it has the color of snake-oil and ultimately ends tasting of snake-oil ... it is most likely snake oil--i.e., a lame duck. (Not even to mention that a partner and I have built a couple! LOL)

However, Barnum and Bailey would be proud!

JS
I have read thru the thread and find nothing that would suggest that
the original poster
cannot do what he states he has done.
By comparing Gaussian law with Maxwell the requirement of his antenna
calls for a system in equilibrium which can be any size ,shape or
elevation. Such a design goes back more than ten years on this
newsgroup when I stated that radiation came in pulses. have described
such as an antenna as one having only distributed loads and where
external lumped loads are imposed during manufacture they must be
cancelled to maintain equilibrium. All of the masters work and
mathematics are based around the requirement of equilibrium law of
Newton i.e addition of all vectors equal zero which is the basis for
no moving charge within a conductor in equilibrium.(this is descibed
in many books or can be googled by inserting current carrying radiator
equilibrium or similar words Root LC in Maxwells equation is

strictly for distributed loads in equilibrium unless the mathematics have changed in the last 150 yearsand does not include lumped loads as part of the laws of other masters from whom he got the mathematics from. If you obtained a helix antenna and lengthened the open end of the helix by continuing the rotation to the starting point ie cancelling the lumped loads you have such an antenna that is not straight and is in a state of equilibrium which provides gain.
Experts, get on Eznec and prove it for yourself, don't just be a talking head !
There are plenty of programs that can simulate such a arrangement without difficulty to simulate a small antenna with full wave dimensions that can provide gains described in his experiments. I have not seen his antenna and suspect that the addition of chokes are supplied because he has not fully cancelled lumped load and thus is trying to prevent feed line radiation which in a lot of cases is not considered a hindrence.
If the wire used is a wavelength long then you can't stop it radiating with respect to its unit length if it is in equilibrium. Period. It is easy to debunk an antenna without reason. It is a lot harder to find error in the mathematics involved which supports such antennas especially when it can easily be proved in practice and checked by anybody. Make it worth my while and I will be happy to prove it $1000dollar bvet was suggested in the past but with no takers. I only ask for conpensation for my costs.

By the way, on my page

unwinantennas.com/

I describe how to make an antenna even smaller than that made by the
threads initial poster
I also supplied SWR measurements for frequencies between 2 and 100
Mhz. The wire I used was a random length and the results should be
duplicated with a couple of wavelengths for the lowest frequency.
Isolated spot frequencies can be attained by the use of a jumper. Such
antennas can also be made in small sheet form and other configurations
Wire used for such antennas do not have to be made of wire with
mechanical thickness since no external mechanical stresses are
involved.
Nuff said. I'm gone !

My point can be summed up quickly; where is this antenna being used in
the commercial sector--it has certainly been around to have gained
interest there, if deserved.

That is all folks ...

Regards,
JS

Because they don't know about it nor does the ARRL
Ham radio is not what it used to be. As the older ones die off the cb
talking heads have gained the majority.
That is why you get the same answers on antennas on this group as you
would get from any woman doing her shopping at the mall.
CB hams are only interested in gain or how loud their heckling voices
can be heard over the voices of others but antennas are a lot more
than that for those really interesred in a hobby rather than bar room
talk. Gates left before he graduated in college to make a lot of money
WRT did the same thing by not graduating from high school yet the
group here give his heckling space because they have nothing better to
offer. Not one person has given good reason why the quoted antenna
cannot work as stated, not one. By mathematics or actually making one
since heckling is regarded as a suitable replacement for true
knowledge now in the present hobby of ham radio. Ham radio is no
longer on the cusp of invention and the world has moved on without

them.Would you allow your children to listen to ham radio at will or look at porn on the computer? The words and conduct now are the same and civility has flown out of the window!

The "protectionism/good-ole-boys-club/religious-devotion-to-arrl/etc. of the old hams have lead us here to this stale/dysfunctional/non-progressive/etc. end(s.) The "cb hams" you refer to are, in all actuality, "appliance user hams." We now reap what has been sown for decades. We always needed good minds, what we got were brass pounders! :-(

>> Gates left before he graduated in college to make a lot of money

College or an "education" has never given anyone what the vast majority think it does. You are either born with the gray matter (IQ) to think for yourself and be notable amongst the unwashed, or you are not. Education simply gives a great mind something to do with itself.

The proof is in the pudding, a buddy and I have built a couple of them (he bought the stupid plans, I DIDN'T!), there are much better designs. And, these designs have been found by industry. See what designs are incorporated into cell phones and towers, in rfid devices, remote tire pressure gauges on cars, wifi devices, remote controls, etc.

This is a sign of the times--gays marrying, breakup of the family,
foster homes, inferior schools, corrupt politicians, etc. The true
cause(s) of the problem(s) you state are too numerous to mention.
Non-civil hams are only a symptom, not the disease ... and the diseases
too numerous to mention themselves ...

Regards,
JS

John you have it down pat! The bands will be taken over by industry or
the military.
There is no way hams will be allowed to keep the bands after it is
seen what they have done to the
hobby. If you have to prevent your children from listening eventually
it will be taken away just like smoking
in the presence of others
Hams will still be able to use their radio but they wont be allowed to
transmit where it affects others.
Just like singing in the shower It just stays in the hamshack
Art
unwinantennas.com/
where they can practice their free speech rights without offending
others.

Actually, I still hold hope that something can be done or will happen to
halt these trends ... but the future scares me--just call me paranoid ...

First of all Felix has placed his project into such a 'top secret'
status that even the contract to which one agrees is secret until
after it is agreed to. When I told Felix I might buy his plans (IIRC
they were only $35.00 at the time) but, I would need to first see the
agreement, he cut off communications with me.

I'll ask Felix again, what are the terms of agreement, or why are they
secret until we paid for the plans?

Because of his secrecy of his agreement, I can only speculate that he
is looking for marks, suckers, or fools to buy his antenna plans.
Only a fool would sign a check and turn it over to a stranger to fill
in as he desires.

Personally, I would love for Felix's antenna design to perform
according to his claims. I would be proud to have his ugly pole on
top of my car as I drive down the road working DX if it works as
claimed. ("ugly pole" is not meant to be derogatory, see my car to
understand.)

And Art, the fact is that only Felix has the obligation of proof. As
I see it, this is the issue:
Felix has made certain claims to a product which he is selling. The
evidence he is using to back up his claims doesn't hold up to the
standards set to establish such claims. He may have tried, as in he
tested his antenna against a loop, but there were discrepancies in his
test that would skew the results.

I think everyone knows that at one time, according to the laws of
aerodynamics, a bumble bee could not fly. The laws have been changed
so the Bumble-bee can now fly. Currently, I believe the general rules
of antenna theory say that a properly made 1/4 wave ground plane will
outperform a ground plane less than 1/10th wavelength in size. (I am
sure some of the EEs here can prove this mathematically or offer some
specific scientific law, but I am not trying to go there.) Felix
claims to have an antenna that can defy this rule, therefore, the
burden of proof lies on him, not the EEs in the group.

I will not say that there is not a design that can break the general rule I stated above, but the evidence Felix is offering is sketchy at best.

No such description is to be found on your page,
just utter nonsense.

>I also supplied SWR measurements for frequencies between 2 and 100

No, you did not provide measurements, you just depict a few graphs
which you faked.

Hi guys,
Does enyone know if exist is a wireless rotator?
I cannot run the control cable between the control box and the rotator.
Any advice is very appreciated.

Thanks

Andrea.

Hi Andrea

I have never seen one. You could of course use a wireless based terminal server RS232 thing. Many of these boxes also have I/O ports to turn things on and off with and some of these even have analog inputs. Cyclades make them but so do a lot of other manufacturers. They are commonly used to extend regular RS232 over an unwired distance. They normally map a local PC virtual serial port to the remote one but you can also just "join" a local RS232 port to the remote one. Kind of like a long serial cable! I would suspect that analog to analog wireless boxes would also be available but havent checked.

Your biggest issue then will be powering the whole system remotely. If you are running separate power wires from the control position there is no reason you couldnt piggy back control signals onto it. In fact with some thought you could put everything onto one piece of coax!

Cheers Bob VK2YQA

I think it's very questionable whether any such "secret contract"
would be enforceable, at least here in the U.S.

One of the crucial elements in a contract is the "meeting of the
minds". That is, the parties who are taking part in the contract must
be in agreement as to what it is that is being agreed to.

Terms which are kept secret from one party to the contract until after
the contract was signed would almost certainly be held to be invalid
and unenforceable.

Felix *could* have a legal and binding contract with buyers of his
antenna which has strict terms that require nondisclosure, forbid
reverse engineering, or insist that buyers do The Dance in public on
alternate Thursdays. However, in order to be enforceable, all of the
terms have to be presented to the buyer *before* the contract is
agreed to.

I haven't seen a commercial rotator with wireless control.

I'm sure it would be possible to adapt a standard rotator system
(rotator module plus control box) to incorporate wireless control.
There are plenty of wireless-control modules available on the market
which can be used to operate small relays - a two-channel wireless
control module could drive a couple of relays which take the place of
the clockwise / counterclockwise directional switches in an existing
rotator controller.

Hi Andrea

Since there is power at the rotator, I assume there are power lines there.
I think you can figure a way to rotate thru an X-10 device.

Jerry

Hi Andrea

If the power for the rotator is related to the AC system that powers your house, you dont need "wireless". There is a common connection already available to you, X-10.

I totally agree.He really should supply a graph of frequency versus
SWR then buyers would know what they are getting.
Hams are not interested in how it works on ly the extent of
frequencies and the external size of the antenna
Isn't this what Rhode Island did. Now if the wire is one wavelength
such that radiation cannot occur from the feed line that would be a
welcome addition.Albiet a balanced to unbanced windings would be handy
for when coax is used.
Either way the antenna seems awefull long compared to what it could
be.
Art

Channel Master makes a remote controlled rotator that works with an IR
remote like TV sets use. It is not a heavy duty unit and it is not
expensive either.

the only time a graph of swr vs frequency is important is for a dummy load.
it is not a measure of antenna performance.

Yes, but how I can see the position of my antenna?
Maybe I'm missing something, but with the X10 I can move the antenna but I
cannot "see" the position.

Andrea.

>cannot "see" the position.

For a lot of the simpler rotator designs (e.g. most TV antenna rotator systems I've seen) there isn't actually any positional feedback at all between the rotator and the control box. The connection is entirely one-directional (controller to rotator).

With these rotators, the position is deduced, rather than measured. The rotator turns at a fairly constant speed when energized in either direction, and its rotation is limited by clutch-stops in both directions. When it's first installed you rotate it in one direction for long enough for it to hit the (e.g.) clockwise stop, then manually align the mast so that it's pointing due north (usually) and tighten the U-bolts.

Thereafter, when you tell the controller to rotate the antenna, the rotator turns the antenna, and a separate motor-gear arrangement turns an indicator on the controller - presumably, at the same rate, so that the indicator shows you something close to the actual antenna position.

The indicator and the antenna can drift out of alignment over time, so it's necessary to resynchronize them occasionally... usually by rotating the antenna for long enough that it hits the end-stop (and is thus pointing north) and then manually adjusting the indicator position on the controller box.

I think that you have two basic choices for your design approach:

- Do a wireless version of this simple arrangement... have your wireless controller (X-10 or whatever) turn the rotator motors on and off, *and* turn on and off a motor- or logic-driven position indicator which deflects at the same angular rate that the rotator moves. Occasionally re-synchronize the antenna and indicator.

- Use a rotator which has a true positional readout (e.g. a potentiometer which can deliver a variable DC voltage, like the Yaesu TailTwister types), plus a bidirectional radio link of some sort. You'd need a couple of bits of control information going from the controller to the rotator (to run the relays), and some sort of analog-proportional coming back down.

The former is probably going to be easier to achieve.

Hi Andrea , You can do yourself a favor by learning X-10. The technology
allows a limitless number of channels. You can, if you want to, control
the rotation with X-10, and also send positoon back thru your AC lines.

5733. Re: 40m centre feed dipole, I want to add 80m

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-30 13:42:52 UTC
From: Andy <dx90@blueyounder.co.uk>
Message-ID: <np5ak.140557$Ek2.23826@newsfe17.ams2>
Source record: 24555

Hi all,

I have now tried all sorts of combinations and the best that I have found to work best in such a small place is a 40m centre fed dipole, fed direct with 40 feet of 50 Ohm RG58 c/u then into a Ugly Balun made of RG58 c/u then into RG213 back to the ATU. This is just how it all worked out, come the end.
I then made a couple of 40 meter traps for 80m.
The 40 meter section of the dipole barely fits the garden with no room to spare. The traps and the added lengths of wire are dropped down and tied back slightly to keep it away from the mounting pole, It is still kept at a right angle to the main part of the antenna.
I have a 1.1:1 - 1.3:1 on the main frequency that I want to use on 40m and 80m without using the ATU.
It seems to work very well for what it is.
Thanks all for your help.

Boy, that would really tell a buyer all he needs to know about
the antenna/dummy load in question.. :/

> Hams are not interested in how it works on ly the extent of
> frequencies and the external size of the antenna

Hummm.. This is an interesting comment from a person who
tries to build the smallest antennas he can, and constantly
harps on the perceived wide bandwidth of said devices.. :/

> Isn't this what Rhode Island did.

How did Rhode Island get involved?
Yes, Rhode Island is a small state. You could even call it puny
compared to the one I live in, but I think they do have enough
room for a full size dipole or loop.. :/
Maybe even a beverage or two..

>Now if the wire is one wavelength
> such that radiation cannot occur from the feed line that would be a
> welcome addition.

Prey tell.. How will the use of a 1 wavelength element eliminate
feed line radiation?

>Albiet a balanced to unbanced windings would be handy
> for when coax is used.

Prey tell why? Would the omission of balanced to unbalanced
windings lead to a disturbance in the force?
How would you explain the obvious success of decoupled verticals
using no "windings" at all?

> Either way the antenna seems awefull long compared to what it could
> be.

He may be trying to avoid dummy load performance from a device
intended to radiate.
I'm sure he'll be happy to let you corner the market in that respect
to avoid any future patent infringements.

5736. Loop antenna success story

Newsgroup: rec.radio.amateur.antenna
Date: 2008-06-30 16:33:55 UTC
From: Michael <micoder@sbcglobal.net>
Message-ID: <TV7ak.176850$qk1.9829@fe02.news.easynews.com>

I live in town, three blocks from a failing transformer. At night you can see it arcing continuously. This produces an S8 noise level on my Icom 718. The power company has been completely uncooperative now for 6 months of my complaining.

Even though I was warned that a loop antenna would not help with a noise source this close, I put up a 75 meter full wave loop anyway. I was desperate.

It was certainly not as easy as putting up my dipole between a couple of trees. I had to add an aluminum mast to my garage.

My loop is tied to three trees and an aluminum mast at 35 feet. My noise level on 75 meters went from S8 to S0.

This antenna is fed out of an old Tentec tuner model 229. It then feeds 25 feet of RG213. It then transitions through a Radio Works remote balun hung from the house into 60 feet of ladder line. The antenna is fed at a corner. The other three corners our outfitted with small pulleys to "float" the wire and compensate for tree movement. The wire is hung loosely to accommodate winds.

All my regular local operators say that my signal went from 20-30 over with my dipole to 40 over with the loop. I realize this does not make sense, because the dipole was radiating all 1000 watts of energy too. I can't figure it out. However, I will not argue with success.

I put up this antenna in hopes of reducing receiver noise. It sure did.

If you have a transformer that you can SEE arcing, and the power company
is not responding to it. You have a much bigger problem than S8 noise!

Wonderful, can you just imagine all the citizens attempting to listen to
SW/AM radio? (lines/noise in broadcast TV, etc.) Seems like you need to
write a nice letter to the editor and let your fellow citizens in on
that xfrmr. If nothing else, those in your area will know why their
favorite radio programs are no longer possible to hear ...

Regards,
JS

If that's really the case and you have any sort of record of your
dealings with the power company, the FCC would like to hear from you.

Better yet, report a potential fire hazard to your local fire
department. You'll get action, and fast. Had a bad transformer near
me that caught on fire.

Better yet, report a potential fire hazard to your local fire
department. You'll get action, and fast. Had a bad transformer near
me that caught on fire.

To get the best results - write a letter to the chairman of the board of the
Electric Company, be sure to send it REGISTERED Return Receipt.

In your letter indicate that since you can't get any service from his
company, (tell them exactly what is happening & that you are a member of the
local RACES/ARES emergency communications group and that you can't
communicate because of the interference), and that If you do not hear from
them with 10 business days that you are going to contact the power
commission of your (county/state) & the FCC and your local congress
people...

The chairman of the board does not like getting those kinds of letters and
usually the CRAP will hit the fan and trickle down very quickly & they
should be calling you to get you out of their hair!

Unless the transformer is actually on fire, most fire depts. won't do any
thing about it - they will just refer you back to the utility.

Best 73's

I don't remember his call, I think he was VP of R&D or Engineering,
not the president. He did have a 20m 10 element Yagi. :-)

I don't think it rotated.

Geoff.

Nyt on maamme tiedotusmonopoleissa tullut tavaksi ved&#xF;tt&#xF;&#xF; esiin sellaisia tietoja, ett&#xF; riisin- ja viljanhinnan nousu johtuisi siit&#xF;, ett&#xF; niit&#xF; k&#xF;ytet&#xF;&#xF;n el&#xF;inrehuina lihantuotantoon.. .Haloo kuka on n&#xF;hnyt "riisirehua"? Veikkaan ett&#xF; kyseess&#xF; on maailman harvinaisin sbesiaalirehupussukka, jota tuskin kukaan on edes n&#xF;hnyt! Jos toi on jo harvinaista niin metanolibensa riisist&#xF; on varmaan jos mahdollista harvinaisempaa. Eli t&#xF;mm&#xF;iset eiv&#xF;t taatusti ole hinnankorotuksen takana. Vaan USA:n s&#xF;&#xF;nn&#xF;stelyriisitilanne johtuu ydinaavikoitumisen jo kolmena vuona pilaaaman sadon kylm&#xF;st&#xF; faktasta!

Suomen kohdalla esitet&#xF;&#xF;&#xF;n samoja biopolttoainesyit&#xF; my&#xF;s. Mik&#xF; on toki my&#xF;s silkkaa ved&#xF;tyst&#xF;. Jokin aika sitten tosin maahamme suuniteltiin bioetanolitehtaita, joita ei noussut. My&#xF;s esim. viljasta maassamme povattiin varsin kohtalaista biopolttoainetta. Kauraa pidettiin varteenotettavana valmiina biopellettin&#xF;. Ainoa mainittava haitta oli viljan paakkuuntuminen poltinp&#xF;&#xF;h&#xF;n kakkuna, jota piti kuulema puhdistella. Varsin pian v&#xF;hin &#xF;&#xF;nin maahamme tehtiin ehk&#xF; historiamme tarkimmin salattu laki. M&#xF;&#xF;r&#xF;ys joka kielsi KAIKEN viljaenergian polttamisen! Tosiaan koko bioenergiahaaveilut lopetettiin kuin maan nielem&#xF;n&#xF;, vaikkei asian totuutta kerrottu kansalle miss&#xF;&#xF;n. Ydinaavikoitumisen viedess&#xF; -40% sadantakadollaan vuodesta toiseen ruuan p&#xF;yd&#xF;st&#xF;mme ei j&#xF;&#xF;nyt vaihtoehtoa. Mutta reaalia t&#xF;st&#xF; ei maatalouspoliittisesta huijaussyyst&#xF; ikin&#xF; tunnustettu. My&#xF;s ydinvoiman kuivamien ja kasvuhaittojen peltojemme totuus pimitettiin mehil&#xF;iskatojen vastaavan syyn lailla. Mutta sain vaan selville tapani mukaan! Joka tapauksessa h&#xF;mm&#xF;stytt&#xF;v&#xF;&#xF;, ett&#xF; meill&#xF; nyt on lakim&#xF;&#xF;r&#xF;yksi&#xF; joita lis&#xF;kseni tuskin moni on tutusti edes kuullut.(

Dear Dave thanks a lot for your very detailed message.
I will think about it and study a little more how ham rotator systems work.
Another idea is to use a pc controlled control box (in Italy we have a good product by Prosistel) connected to my pc usign a serial wireless extender adapter, but I have to check the range covered by the wireless. I'm at the first floor and the antenna is at the 4th floor.
Thanks again!

Andrea.

Kun katsoo n�it�keskeisimpi� nettilinjo, niin alkuun n�ytt�� silt�, ett� t��ll� palloilee l�hinn� "ruinruinit, muiden mollaajat, ja ostetut ydinlobbarit". Eli suoraan sanottuna yht� tyhj�n kansa pelailevia palloilijoita. Mutta siten huomaa miksi ihmiset t�nne niin mielell��n tulee viisaukasia silti lukemaan?

Jos osut talous-, yhteiskunta- ja poliittiselle sektorille huomaat, miten siel� toimii my�s porukoissa suoranaisia "kassamangneetteja". Olen avoimesti kiitellyt mm Rauno Kankaan miten kristalloisin. ..no hei vaikka "eettist� asennekoulutustyyli��n". Kaveri jos kuka on ollut oiva esimerkki siit� miten nettiammattilaisen tulisi k�ytt�yty�. Aina asiallisena, kaikesta "oskukarstasta" huolimatta tied�t saavasi tukun paikoin jopa el�m�� suurempaa osviittaa ja paikoin jopa nerokasta osviittaa siit� miten maailma makaa kritiikkiin asti. Oivan ja loisteliaan materiaalin saat t��lt� ilmaiseksi, neuvoja on tuohtumaton j�m�k�n asiallinen. Hienoa, juuri t�t� tuhannet t��lt� haluaa.

No tottakai ei finetti tyyli ole j�tt�nyt kylm�ksi, vaan h�nen vision��risyytt��n sitten kopioidaan my�s muutamissa muissa osastoissa, ja hyv� niin. Tietysti kopio on kopio, mutta tusinan verran t��lt� l�ytyy sellaisia kirjoittelijoita, joista heijastuu Raunon oivallinen esimerkkijatkumo. Ja jopa kyky kampittaa my�s Raunoon liittyv�t pakolliset h�irik�ainekset. Joita voidaan mainita yhteisnimill��n, "Oskut, ydinklingonit ja vastaavat". Er�s henkil� jonka sattuneesti haluan ilmoittaa t�ss� on nimimerkki NEO. H�n ei toki ole talous-, poliittis-, yhteiskuntasektoreilla tietysti esikuvansa luokkaa, ei toki. Mutta kampittaa kyll� muutamilla sektoreillaan my�s suvereeneill� erikoisaloillaan. Ja totta kai taitojensa h�ikimi� ns. "ydinklingoneita ja SUPO-sotkijoita on toisinaan niin suuret parvet kintereill��n, ettei rahanjaolla tunnu TVO/Posivalla olevan rajoja h�irikk�sahureittensa palkkaamisiin. Mutta siin� NEO on kyll� kykyis� Raunon rinnalla toki, ett� ammattiviisautta, viile�� asiallisuutta ja ennenkaikkea loputtoman ammattitaitoista materiaalia saamme saavikaupalla k�ytt��mme!

Suuri yleis� nauttii ja nettioperaattorit kiitt�� valtaisien hittim��rien aina vaan jaksaessa yll�tt��. Netti el�� kiistatta vain muutaman t�llaisen "gurun" �lyn neuvokkuudella. Kansanmassat saa mit� haluaa. Ja operaattorien maireat ilmeet kertovat valtaisien suosikkim��rien alati pit�v�n systremit hengiss�. Ennenkaikkea koko t�m� kaikki yhdess� n�kyy aivan k�sitt�m�tt�m�sti kumuloituvine kansan ymm�rryskykykasvuina. Nyt on massoilla kanava k�yt�ss�, jossa ei iso raha pyki. Ei valtiomoinoliitit kuki seinill�. Vaan asiafaktan kiinisaanti on huomattu iloisesti jopa laajasti rajojemme ulkopuolelle asti. Kuten hyvin tied�mme asiallista kritiiki� ei valtiomonopolit salli. Ei SUPO/TVO/kuin edes hallitusmokailijat eduskunnan

helsinkil�is�kyj� my�ten. Nettien palstat pursuaa JUURI t�st�, ett� on maamme ehdottomasti viimeinen vapaamman tiedon periferia sitke�sti. Jopa niin sitke�sti, ett� SUPO/NSA/STUK/ TVO/Posiva/Fortum /GTK ja monet , monet muut uhkailevat aivan h�rskisti tappaa koko kanavan! Heid�n edustamansa valtiorappiollinen m�d�nn�isyys kun ei kansan viisastuessa ja tietoa saadessa en�� totuuksia sied�. Sis�ministeri�n tuhatp�isen poliisisikailukulttuurin uhka on jo pitk��n ollut nettituhoa hautomassa. Saa vaan n�hd� kest��k� systeemimme nimenomaan Suomessa totuuden puhujia?

5752. Re: 40m centre feed dipole, I want to add 80m

Thanks for the feedback Andy. It's somewhat rare to find out exactly how a
project turned out on this forum :-)

Regards

Mike G0ULI
